ADAPTIVE FINITE ELEMENT METHODS FOR MIXED CONTROL-STATE CONSTRAINED OPTIMAL CONTROL PROBLEMS FOR ELLIPTIC BOUNDARY VALUE PROBLEMS

R.H.W. HOPPE AND M. KIEWEG

ABSTRACT. Mixed control-state constraints are used as a relaxation of originally state constrained optimal control problems for partial differential equations to avoid the intrinsic difficulties arising from measure-valued multipliers in the case of pure state constraints. In particular, numerical solution techniques known from the pure control constrained case such as active set strategies and interior-point methods can be used in an appropriately modified way. However, the residual-type a posteriori error estimators developed for the pure control constrained case can not be applied directly. It is the essence of this paper to show that instead one has to resort to that type of estimators known from the pure state constrained case. Up to data oscillations and consistency error terms, they provide efficient and reliable estimates for the discretization errors in the state, a regularized adjoint state, and the control. A documentation of numerical results is given to illustrate the performance of the estimators.

Keywords: distributed optimal control problems, mixed control-state constraints, adaptive finite elements, a posteriori error analysis,

AMS/MOS Classification: 65N30, 65N50; 49K20, 65K10

1. INTRODUCTION

Adaptive finite element methods based on reliable a posteriori error estimators are powerful algorithmic tools for the efficient numerical solution of boundary and initial-boundary value problems for partial differential equations (PDEs) (cf. [1, 3, 4, 14, 35, 41] and the references therein). On the other hand, considerably less work has been done with regard to optimal control problems for PDEs. The so-called goal oriented dual weighted approach has been applied in the unconstrained case in [4, 5] and to control constrained problems in [20, 42], whereas

Date: April 9, 2007.

residual-type a posteriori error estimators for control constrained problems have been derived and analyzed in [16, 17, 21, 25, 28, 30, 31]. Unlike the control constrained case, pointwise state constrained optimal control problems are much more difficult to handle due to the fact that the Lagrange multiplier for the state constraints lives in a measure space (see, e.g., [8, 9, 23, 39]). Therefore, it is a natural idea to regularize state constrained problems by means of mixed control-state constrained ones, since with regard to numerical solution techniques the regularized problems can be formally treated as in the case of pure control constraints (cf. e.g., [2, 11, 33, 36, 37, 38, 39, 40]). However, so far an a posteriori error analysis of adaptive finite element approximations has not been provided for mixed control-state constrained control problems.

In this paper, we will be concerned with the development, analysis and implementation of a residual type a posteriori error estimator for mixed control-state constrained distributed optimal control problems for linear second order elliptic boundary value problems. The paper is organized as follows: In section 2, as a model problem we consider a distributed optimal control problem for a two-dimensional, second order elliptic PDE with a quadratic objective functional and mixed unilateral constraints on the state and on the control. The optimality conditions are stated in terms of the state, the adjoint state, the control, and a Lagrangian multiplier for the mixed constraints. It is, however, not possible to use the residual-type a posteriori error analysis for pure control constrained problems, since the reliability and efficiency estimates involve constants that blow up when the regularization parameter goes to zero. Instead, one has to adopt the error analysis as developed for the pure state constrained case [26]. In this spirit, we further consider a regularized multiplier and a regularized adjoint state which will play an essential role in the error analysis. In section 3, we describe the finite element discretization of the control problem with respect to a family of shape regular simplicial triangulations of the computational domain using continuous, piecewise linear finite elements for the state, the control, and for the adjoint and the regularized adjoint state. In section 4, we present the residual-type a posteriori error estimator for the global discretization errors in the state, the regularized adjoint state, and the control. Data oscillations and consistency errors are considered as well, since they enter the subsequent error analysis. In section 5, we prove reliability of the error estimator, i.e., we show that it gives rise to an upper bound for the global discretization errors up to data oscillations and consistency errors. Section 6 is devoted to the efficiency of the

estimator by showing that, modulo data oscillations, the error estimator also provides a lower bound for the discretization errors. Finally, section 7 contains a documentation of numerical results for two representative test examples in terms of the convergence history of the adaptive finite element process.

2. THE MIXED CONTROL-STATE CONSTRAINED DISTRIBUTED CONTROL PROBLEM

Let Ω be a bounded domain in \mathbb{R}^2 with boundary $\Gamma := \Gamma_D \cup \Gamma_N$, $\Gamma_D \cap \Gamma_N = \emptyset$. We use standard notation from Lebesgue and Sobolev space theory. In particular, we refer to $L^2(\Omega)$ as the Hilbert space of square integrable functions with inner product $(\cdot, \cdot)_{0,\Omega}$ and associated norm $\|\cdot\|_{0,\Omega}$. We denote by $L^2_+(\Omega)$ the non-negative cone of $L^2(\Omega)$, i.e., $L^2_+(\Omega) := \{v \in L^2(\Omega) | v(x) \geq 0 \text{ f.a.a. } x \in \Omega\}$. Moreover, $H^k(\Omega)$, $k \in \mathbb{N}$, stands for the Sobolev space of square integrable functions whose weak derivatives up to order k are square integrable as well, equipped with the norm $\|\cdot\|_{k,\Omega}$. $H_0^k(\Omega)$ denotes its subspace $H_0^k(\Omega) := \{v \in H^k(\Omega) | D^\alpha v|_\Gamma = 0, |\alpha| \leq k-1\}$ and $H^{-k}(\Omega)$ is the dual of $H_0^k(\Omega)$.

For given $c \in \mathbb{R}_+$, we refer to $A : V \rightarrow H^{-1}(\Omega)$, $V := \{v \in H^1(\Omega) | v|_{\Gamma_D} = 0\}$, as the linear second order elliptic differential operator

$$Ay := -\Delta y + cy \quad , \quad y \in V$$

and to $a(\cdot, \cdot) : V \times V \rightarrow \mathbb{R}$ with $a(y, v) := \int_\Omega (\nabla y \cdot \nabla v + cyv) dx$ as the associated bilinear form. We assume $c > 0$ or $\text{meas}(\Gamma_D) \neq 0$. In particular, this assures that A is bounded and V -elliptic, i.e., there exist constants $C > 0$ and $\gamma > 0$ such that

$$(2.1) \quad |a(y, v)| \leq C \|y\|_{1,\Omega} \|v\|_{1,\Omega} \quad , \quad a(y, y) \geq \gamma \|y\|_{1,\Omega}^2 \quad .$$

Now, given a desired state $y^d \in L^2(\Omega)$, a shift control $u^d \in L^2(\Omega)$, regularization parameters $\alpha > 0, \varepsilon > 0$, and a function $\psi \in L^\infty(\Omega)$, we consider the objective functional

$$(2.2) \quad J(y, u) := \frac{1}{2} \|y - y^d\|_{0,\Omega}^2 + \frac{\alpha}{2} \|u - u^d\|_{0,\Omega}^2$$

and the mixed control-state constrained distributed optimal control problem: Find $(y, u) \in V \times L^2(\Omega)$ such that

$$(2.3a) \quad \inf_{y,u} J(y, u) \quad ,$$

subject to the constraints

$$(2.3b) \quad Ay = u \quad \text{in } \Omega, \quad y = 0 \quad \text{on } \Gamma_D, \quad \boldsymbol{\nu} \cdot \nabla y = 0 \quad \text{on } \Gamma_N,$$

$$(2.3c) \quad \varepsilon u + y \in K := \{v \in L^2(\Omega) \mid v(x) \leq \psi(x) \text{ f.a.a. } x \in \Omega\}.$$

The usual way to look at (2.3a)-(2.3c) is as a regularized state constrained problem, since the multiplier associated with the inequality constraint (2.3c), usually called the adjoint control for control constrained problems, lives in the non-negative cone of $L^2(\Omega)$ and not in a measure space as in the case of pure state constraints. Obviously, the latter case is much more difficult to handle.

We define $G : L^2(\Omega) \rightarrow V$ as the control-to-state map which assigns to $u \in L^2(\Omega)$ the unique solution $y = y(u)$ of (2.3b). We note that the control-to-state map G is a bounded linear operator. Substituting the state $y = y(u)$ by $y(u) = Gu$ leads to the reduced objective functional

$$(2.4) \quad J_{red}(u) := \frac{1}{2} \|Gu - y^d\|_{0,\Omega}^2 + \frac{\alpha}{2} \|u - u^d\|_{0,\Omega}^2,$$

and the mixed control-state constrained problem (2.3a)-(2.3c) can be restated as

$$(2.5) \quad \inf_{\varepsilon u + Gu \in K} J_{red}(u).$$

Standard arguments from convex optimization reveal the existence and uniqueness of a solution. The optimality conditions for the optimal solution $(y, u) \in V \times L^2(\Omega)$ are as follows.

Theorem 2.1. *The optimal solution $(y, u) \in V \times L^2(\Omega)$ of (2.3) is characterized by the existence of an adjoint state $p \in V$, and a multiplier $\sigma \in L^2_+(\Omega)$ such that*

$$(2.6a) \quad (\nabla y, \nabla v)_{0,\Omega} + (cy, v)_{0,\Omega} = (u, v)_{0,\Omega}, \quad v \in V,$$

$$(2.6b) \quad (\nabla p, \nabla w)_{0,\Omega} + (cp, w)_{0,\Omega} = (y - y^d, w)_{0,\Omega} + (\sigma, w)_{0,\Omega}, \quad w \in V,$$

$$(2.6c) \quad p + \alpha(u - u^d) + \varepsilon\sigma = 0,$$

$$(2.6d) \quad (\sigma, \varepsilon u + y - \psi)_{0,\Omega} = 0.$$

The residual-type a posteriori error analysis known from the pure control constrained case [21] is not applicable to (2.6a)-(2.6d) uniformly in the regularization parameter ε , since the constants in the reliability and efficiency estimates for the associated error estimator depend on ε in the sense that they blow up as $\varepsilon \rightarrow 0$. Instead, the a posteriori error analysis has to be adopted to that what is known from the pure state

constrained case. Following [26], we define a regularized multiplier $\bar{\sigma} \in V$ as the solution of

$$(2.7) \quad (\nabla \bar{\sigma}, \nabla v)_{0,\Omega} + (c\bar{\sigma}, v)_{0,\Omega} = (\sigma, v)_{0,\Omega} \quad , \quad v \in V \quad ,$$

and further introduce a regularized adjoint state $\bar{p} \in V$ according to

$$(2.8) \quad (\nabla \bar{p}, \nabla v)_{0,\Omega} + (c\bar{p}, v)_{0,\Omega} = (y - y^d, v)_{0,\Omega} \quad , \quad v \in V.$$

Obviously, p , \bar{p} , and $\bar{\sigma}$ are related by

$$(2.9) \quad p := \bar{p} + \bar{\sigma}.$$

3. FINITE ELEMENT APPROXIMATION

We consider a family $\{\mathcal{T}_\ell(\Omega)\}$ of shape-regular simplicial triangulations of Ω which align with Γ_D, Γ_N on Γ . We denote by $\mathcal{N}_\ell(D)$ and $\mathcal{E}_\ell(D)$, $D \subseteq \bar{\Omega}$, the sets of vertices and edges of $\mathcal{T}_\ell(\Omega)$ in $D \subseteq \bar{\Omega}$, and we refer to h_T and $|T|$ as the diameter and the area of an element $T \in \mathcal{T}_\ell(\Omega)$, whereas h_E stands for the length of an edge $E \in \mathcal{E}_\ell(D)$. For $E \in \mathcal{E}_\ell(\Omega)$ such that $E = T_+ \cap T_-$, $T_\pm \in \mathcal{T}_\ell(\Omega)$, we define $\omega_E := T_+ \cup T_-$. For $T \in \mathcal{T}_\ell(\Omega)$ and $E \in \mathcal{E}_\ell(\Omega)$ we further denote by $\lambda_i(T)$, $1 \leq i \leq 3$, and $\lambda_i(E)$, $1 \leq i \leq 2$, the barycentric coordinates associated with the vertices of T and E , respectively. We will also use the following notation: If A and B are two quantities, then $A \lesssim B$ means that there exists a positive constant C such that $A \leq CB$, where C only depends on the shape regularity of the triangulations, but not on their granularities.

The mixed control-state constrained optimal control problem (2.3a)-(2.3c) is discretized by continuous piecewise linear finite elements with respect to the triangulation $\mathcal{T}_\ell(\Omega)$. In particular, we refer to $S_\ell := \{v_\ell \in C_0(\Omega) \mid v_\ell|_T \in P_1(T) \text{ , } T \in \mathcal{T}_\ell(\Omega)\}$ as the finite element space spanned by the canonical nodal basis functions φ_ℓ^p , $p \in \mathcal{N}_\ell(\Omega)$, associated with the nodal points in $\bar{\Omega}$ and to V_ℓ as its subspace $V_\ell := \{v_\ell \in S_\ell \mid v_\ell|_{\Gamma_D} = 0\}$.

Given some approximation $u_\ell^d \in S_\ell$ of u^d and $\psi_\ell \in S_\ell$ of ψ , we refer to $J_\ell : V_\ell \times S_\ell \rightarrow \mathbb{R}$ as the discrete objective functional

$$(3.1) \quad J_\ell(y_\ell, u_\ell) := \frac{1}{2} \|y_\ell - y^d\|_{0,\Omega}^2 + \frac{\alpha}{2} \|u_\ell - u_\ell^d\|_{0,\Omega}^2 .$$

The finite element approximation of the mixed control-state constrained optimal control problem (2.3a)-(2.3c) reads as follows:

Find $(y_\ell, u_\ell) \in V_\ell \times S_\ell$ such that

$$(3.2a) \quad \inf_{y_\ell, u_\ell} J_\ell(y_\ell, u_\ell) \quad ,$$

subject to the constraints

$$(3.2b) \quad (\nabla y_\ell, \nabla v_\ell)_{0,\Omega} + (cy_\ell, v_\ell)_{0,\Omega} = (u_\ell, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell,$$

$$(3.2c) \quad \varepsilon u_\ell + y_\ell \in K_\ell := \{v_\ell \in S_\ell \mid v_\ell \leq \psi_\ell\}.$$

As in the continuous setting, the discrete state constrained optimal control problem (3.2a)-(3.2c) admits a unique solution $(y_\ell, u_\ell) \in V_\ell \times S_\ell$. We obtain the discrete optimality conditions:

Theorem 3.1. *Let $(y_\ell, u_\ell) \in V_\ell \times S_\ell$ be the unique solution of (3.2a)-(3.2c). Then, there exist a discrete adjoint state $p_\ell \in V_\ell$ as well as a discrete multiplier $\sigma_\ell \in V_\ell \cap L^2_+(\Omega)$ such that*

$$(3.3a) \quad (\nabla y_\ell, \nabla v_\ell)_{0,\Omega} + (cy_\ell, v_\ell)_{0,\Omega} = (u_\ell, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell,$$

$$(3.3b) \quad (\nabla p_\ell, \nabla v_\ell)_{0,\Omega} + (cp_\ell, v_\ell)_{0,\Omega} = (y_\ell - y^d, v_\ell)_{0,\Omega} + (\sigma_\ell, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell,$$

$$(3.3c) \quad p_\ell + \alpha(u_\ell - u_\ell^d) + \varepsilon \sigma_\ell = 0,$$

$$(3.3d) \quad (\sigma_\ell, \varepsilon u_\ell + y_\ell - \psi_\ell)_{0,\Omega} = 0.$$

As in section 2 before, we introduce a regularized discrete multiplier $\bar{\sigma}_\ell \in V_\ell$ as the solution of

$$(3.4) \quad (\nabla \bar{\sigma}_\ell, \nabla v_\ell)_{0,\Omega} + (c\bar{\sigma}_\ell, v_\ell)_{0,\Omega} = (\sigma_\ell, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell,$$

and define $\bar{p}_\ell \in V_\ell$ as the solution of the discrete analogue of (2.8), i.e.,

$$(3.5) \quad (\nabla \bar{p}_\ell, \nabla v_\ell)_{0,\Omega} + (c\bar{p}_\ell, v_\ell)_{0,\Omega} = (y_\ell - y^d, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell.$$

As in the continuous setting, we obtain the fundamental relationship

$$(3.6) \quad p_\ell = \bar{p}_\ell + \bar{\sigma}_\ell.$$

We further define $\mathcal{A}(y_\ell)$ and $\mathcal{I}(y_\ell)$ as the discrete active and inactive sets according to

$$\begin{aligned} \mathcal{A}(y_\ell) &:= \bigcup \{ T \in \mathcal{T}_\ell(\Omega) \mid y_\ell(p) = \psi_\ell(p) \quad , \quad p \in \mathcal{N}_\ell(T) \} \quad , \\ \mathcal{I}(y_\ell) &:= \mathcal{T}_\ell(\Omega) \setminus \mathcal{A}(y_\ell) \quad . \end{aligned}$$

4. THE RESIDUAL TYPE ERROR ESTIMATOR

The residual-type a posteriori error estimator involves estimators of the state y and of the regularized adjoint state \bar{p} according to

$$(4.1) \quad \eta_\ell := \eta_\ell(y) + \eta_\ell(\bar{p}).$$

where $\eta_\ell(y)$ and $\eta_\ell(\bar{p})$ consist of element and edge residuals

$$(4.2a) \quad \eta_\ell(y) := \left(\sum_{T \in \mathcal{T}_\ell(\Omega)} \eta_T^2(y) + \sum_{E \in \mathcal{E}_\ell(\Omega)} \eta_E^2(y) \right)^{1/2},$$

$$(4.2b) \quad \eta_\ell(\bar{p}) := \left(\sum_{T \in \mathcal{T}_\ell(\Omega)} \eta_T^2(\bar{p}) + \sum_{E \in \mathcal{E}_\ell(\Omega)} \eta_E^2(\bar{p}) \right)^{1/2}.$$

The element residuals $\eta_T(y)$ and $\eta_T(\bar{p})$, $T \in \mathcal{T}_\ell(\Omega)$, are weighted element-wise L^2 -residuals with respect to the strong form of the state equation (2.3b) and the modified adjoint state equation (2.8), respectively:

$$(4.3a) \quad \eta_T(y) := h_T \|cy_\ell - u_\ell\|_{0,T}, \quad T \in \mathcal{T}_\ell(\Omega),$$

$$(4.3b) \quad \eta_T(\bar{p}) := h_T \|c\bar{p}_\ell - (y_\ell - y^d)\|_{0,T}, \quad T \in \mathcal{T}_\ell(\Omega).$$

The edge residuals $\eta_E(y)$ and $\eta_E(\bar{p})$, $E \in \mathcal{E}_\ell(\Omega)$, are weighted L^2 -norms of the jumps $\nu_E \cdot [\nabla y_\ell]$ and $\nu_E \cdot [\nabla \bar{p}_\ell]$ of the normal derivatives across the interior edges

$$(4.4a) \quad \eta_E(y) := h_E^{1/2} \|\nu_E \cdot [\nabla y_\ell]\|_{0,E}, \quad E \in \mathcal{E}_\ell(\Omega),$$

$$(4.4b) \quad \eta_E(\bar{p}) := h_E^{1/2} \|\nu_E \cdot [\nabla \bar{p}_\ell]\|_{0,E}, \quad E \in \mathcal{E}_\ell(\Omega).$$

Denoting by $y_\ell^d \in S_\ell$ some approximation of the desired state y^d , we further have to take into account data oscillations with respect to the data u^d, y^d, ψ of the problem

$$(4.5) \quad osc_\ell := \left(osc_\ell^2(u^d) + osc_\ell^2(y^d) + osc_\ell^2(\psi) \right)^{1/2},$$

where $osc_\ell(u^d)$, $osc_\ell(y^d)$, and $osc_\ell(\psi)$ are given by

$$(4.6a) \quad osc_\ell(u^d) := \left(\sum_{T \in \mathcal{T}_\ell(\Omega)} osc_T^2(u^d) \right)^{1/2},$$

$$osc_T(u^d) := \|u^d - u_\ell^d\|_{0,T}, \quad T \in \mathcal{T}_\ell(\Omega),$$

$$(4.6b) \quad osc_\ell(y^d) := \left(\sum_{T \in \mathcal{T}_\ell(\Omega)} osc_T^2(y^d) \right)^{1/2},$$

$$osc_T(y^d) := h_T \|y^d - y_\ell^d\|_{0,T}, \quad T \in \mathcal{T}_\ell(\Omega),$$

$$(4.6c) \quad osc_\ell(\psi) := \left(\sum_{T \in \mathcal{T}_\ell(\Omega)} osc_T^2(\psi) \right)^{1/2},$$

$$osc_T(\psi) := \|\psi - \psi_\ell\|_{0,T}, \quad T \in \mathcal{T}_\ell(\Omega).$$

We will show that, up to data oscillations and consistency errors, the residual-type a posteriori error estimator (4.1) provides an upper and

a lower bound for the discretization errors in the state, the regularized adjoint state, and the control which are given by

$$(4.7) \quad e_y := y - y_\ell \quad , \quad e_{\bar{p}} := \bar{p} - \bar{p}_\ell \quad , \quad e_u := u - u_\ell.$$

In much the same way as in case of adaptive finite element discretizations of pure state constrained elliptic boundary value problems (cf. [26]), the a posteriori error analysis requires an auxiliary state $y(u_\ell) \in V$ and an auxiliary adjoint state $\bar{p}(y_\ell) \in V$. These are defined as the solutions of the following variational equations

$$(4.8a) \quad (\nabla y(u_\ell), \nabla v)_{0,\Omega} + (cy(u_\ell), v)_{0,\Omega} = (u_\ell, v)_{0,\Omega} \quad , \quad v \in V,$$

$$(4.8b) \quad (\nabla \bar{p}(y_\ell), \nabla v)_{0,\Omega} + (c\bar{p}(y_\ell), v)_{0,\Omega} = (y_\ell - y^d, v)_{0,\Omega} \quad , \quad v \in V.$$

We further introduce an auxiliary discrete state $y_\ell(u) \in V_\ell$ as the solution of the finite dimensional variational problem

$$(4.9) \quad (\nabla y_\ell(u), \nabla v_\ell)_{0,\Omega} + (cy_\ell(u), v_\ell)_{0,\Omega} = (u, v_\ell)_{0,\Omega} \quad , \quad v_\ell \in V_\ell.$$

The auxiliary states $y(u_\ell) \in V$ and $y_\ell(u) \in V_\ell$ do not necessarily satisfy the state constraints, i.e., it may happen that $\varepsilon u + y(u_\ell) \notin K$ or $\varepsilon u_\ell + y_\ell(u) \notin K_\ell$. Therefore, we introduce the consistency errors

$$(4.10a) \quad e_c^{(1)}(\psi, \psi_\ell) := \max((\sigma - \sigma_\ell, \psi - \psi_\ell)_{0,\Omega}, 0)$$

$$(4.10b) \quad e_c^{(2)}(u, u_\ell) := \max((\sigma_\ell, \varepsilon u_\ell + y_\ell(u) - \psi_\ell)_{0,\Omega} + (\sigma, \varepsilon u + y(u_\ell) - \psi)_{0,\Omega}, 0).$$

Obviously, $e_c^{(1)}(\psi, \psi_\ell) = 0$ for $\psi = \psi_\ell$. Moreover, we note that for $u = u_\ell$ we have $e_c^{(2)}(u, u_\ell) = 0$, since in this case $y(u_\ell) = y$ and $y_\ell(u) = y_\ell$, and hence, $e_c^{(2)}(u, u_\ell) = 0$ due to (2.6d) and (3.3d). We thus define

$$(4.11a) \quad \tilde{e}_c^{(1)}(\psi, \psi_\ell) := \begin{cases} e_c^{(1)}(\psi, \psi_\ell) / \|\psi - \psi_\ell\|_{0,\Omega} \quad , \quad \psi \neq \psi_\ell \\ 0 \quad , \quad \psi = \psi_\ell \end{cases} \quad ,$$

$$(4.11b) \quad \tilde{e}_c^{(2)}(u, u_\ell) := \begin{cases} e_c^{(2)}(u, u_\ell) / \|u - u_\ell\|_{0,\Omega} \quad , \quad u \neq u_\ell \\ 0 \quad , \quad u = u_\ell \end{cases} \quad .$$

The refinement of a triangulation $\mathcal{T}_\ell(\Omega)$ is based on bulk criteria that have been previously used in the convergence analysis of adaptive finite element for nodal finite element methods [13, 34]. For the mixed control-state constrained optimal control problem under consideration, the bulk criteria are as follows: Given universal constants $\Theta_i \in (0, 1)$, $1 \leq i \leq 5$, we create a set of edges $\mathcal{M}_E \subset \mathcal{E}_h(\Omega)$ and sets of elements $\mathcal{M}_{\eta,T}, \mathcal{M}_{u^d,T}, \mathcal{M}_{y^d,T}, \mathcal{M}_{\psi,T} \subset \mathcal{T}_\ell(\Omega)$ such that

$$\Theta_1 \sum_{E \in \mathcal{E}_\ell(\Omega)} \left(\eta_E^2(y) + \eta_E^2(\bar{p}) \right) \leq \sum_{E \in \mathcal{M}_E} \left(\eta_E^2(y) + \eta_E^2(\bar{p}) \right),$$

$$\begin{aligned}
 \Theta_2 \quad \sum_{T \in \mathcal{T}_\ell(\Omega)} \left(\eta_T^2(y) + \eta_T^2(\bar{p}) \right) &\leq \sum_{T \in \mathcal{M}_{\eta,T}} \left(\eta_T^2(y) + \eta_T^2(\bar{p}) \right), \\
 \Theta_3 \quad \sum_{T \in \mathcal{T}_\ell(\Omega)} \text{osc}_T^2(u^d) &\leq \sum_{T \in \mathcal{M}_{u^d,T}} \text{osc}_T^2(u^d), \\
 \Theta_4 \quad \sum_{T \in \mathcal{T}_\ell(\Omega)} \text{osc}_T^2(y^d) &\leq \sum_{T \in \mathcal{M}_{y^d,T}} \text{osc}_T^2(y^d), \\
 \Theta_5 \quad \sum_{T \in \mathcal{T}_\ell(\Omega)} \text{osc}_T^2(\psi) &\leq \sum_{T \in \mathcal{M}_{\psi,T}} \text{osc}_T^2(\psi).
 \end{aligned}$$

The bulk criteria are realized by a greedy algorithm (cf., e.g., [21]). We set

$$\mathcal{M}_T := \mathcal{M}_{\eta,T} \cup \mathcal{M}_{u^d,T} \cup \mathcal{M}_{y^d,T} \cup \mathcal{M}_{\psi,T}$$

and refine an element $T \in \mathcal{T}_\ell(\Omega)$ by bisection (i.e., by joining the midpoint of the longest edge with the opposite vertex), if $T \in \mathcal{M}^T$ and an edge $E \in \mathcal{E}_\ell(T)$ by bisection (joining its midpoint with the opposite vertices of the adjacent elements), if $E \in \mathcal{M}^E$.

Denoting by $\mathcal{N}_T := \{T' \in \mathcal{T}_\ell(\Omega) | T' \cap T \neq \emptyset\}$ the set of all neighboring triangles of $T \in \mathcal{T}_\ell(\Omega)$, we define the set

$$\mathcal{F}_\ell(y_\ell) := \partial\mathcal{A}(y_\ell) \cup \partial\mathcal{I}(y_\ell),$$

where

$$\begin{aligned}
 \partial\mathcal{A}(y_\ell) &:= \bigcup \{T \subset \mathcal{A}(y_\ell) \mid \mathcal{N}_T \cap \mathcal{I}(y_\ell) \neq \emptyset\}, \\
 \partial\mathcal{I}(y_\ell) &:= \bigcup \{T \subset \mathcal{I}(y_\ell) \mid \mathcal{N}_T \cap \mathcal{A}(y_\ell) \neq \emptyset\}.
 \end{aligned}$$

The set $\mathcal{F}_\ell(y_\ell)$ represents a neighborhood of the discrete free boundary between the discrete active and inactive sets $\mathcal{A}(y_\ell)$ and $\mathcal{I}(y_\ell)$. In order to guarantee a sufficient resolution of the continuous free boundary between $\mathcal{A}(y)$ and $\mathcal{I}(y)$, at each refinement step, the elements $T \in \mathcal{F}_\ell(u_\ell)$ are refined by bisection.

5. RELIABILITY OF THE ERROR ESTIMATOR

We prove reliability of the residual-type error estimator (4.1) in the sense that it provides an upper bound for the discretization errors $e_y, e_u,$ and $e_{\bar{p}}$ up to the data oscillations $\text{osc}_\ell(u^d)$ and $\text{osc}_\ell(\psi)$ and the consistency errors $\tilde{e}_c^{(2)}(u, u_\ell)$ and $\tilde{e}_c^{(1)}(\psi, \psi_\ell)$.

Theorem 5.1. *Let (y, u, p, σ) and $(y_\ell, u_\ell, p_\ell, \sigma_\ell)$ be the solutions of (2.6a)-(2.6d) and (3.3a)-(3.3d) and let η_ℓ , $\text{osc}_\ell(u^d)$ and $\tilde{e}_c^{(2)}(u, u_\ell)$ as well as $\tilde{e}_c^{(1)}(\psi, \psi_\ell)$ be the error estimator, the data oscillation in the shift*

control, and the consistency errors according to (4.1),(4.6) and (4.11), respectively. Further, let \bar{p} and \bar{p}_ℓ be the regularized adjoint states as given by (2.8),(3.5). Then, there holds

$$(5.1) \quad \begin{aligned} \|e_y\|_{1,\Omega} + \|e_u\|_{0,\Omega} + \|e_{\bar{p}}\|_{1,\Omega} &\lesssim \\ &\lesssim \eta + \text{osc}_\ell(u^d) + \text{osc}_\ell(\psi) + \tilde{e}_c^{(1)}(\psi, \psi_\ell) + \tilde{e}_c^{(2)}(u, u_\ell). \end{aligned}$$

The proof of Theorem 5.1 will be given by the following three Lemmas 5.2, 5.3 and 5.4.

Lemma 5.2. In addition to the assumptions of Theorem 5.1 let $y(u_\ell)$ and $\bar{p}(y_\ell)$ be the auxiliary state and auxiliary adjoint state according to (4.8a),(4.8b). Then, there holds

$$(5.2) \quad \|e_y\|_{1,\Omega} + \|e_{\bar{p}}\|_{1,\Omega} \lesssim \|y(u_\ell) - y_\ell\|_{1,\Omega} + \|\bar{p}(y_\ell) - \bar{p}_\ell\|_{1,\Omega} + \|e_u\|_{0,\Omega}.$$

Proof. Obviously, e_y and $e_{\bar{p}}$ can be estimated from above by

$$(5.3a) \quad \|e_y\|_{1,\Omega} \leq \|y - y(u_\ell)\|_{1,\Omega} + \|y(u_\ell) - y_\ell\|_{1,\Omega},$$

$$(5.3b) \quad \|e_{\bar{p}}\|_{1,\Omega} \leq \|\bar{p} - \bar{p}(y_\ell)\|_{1,\Omega} + \|\bar{p}(y_\ell) - \bar{p}_\ell\|_{1,\Omega}.$$

Setting $v = y - y(u_\ell)$ in (2.6a),(4.8a), and $M := 1/\gamma$ with γ from (2.1), for the first term on the right-hand side in (5.3a) we readily get

$$\|y - y(u_\ell)\|_{1,\Omega}^2 \leq M \|e_u\|_{0,\Omega} \|y - y(u_\ell)\|_{0,\Omega} \leq M \|e_u\|_{0,\Omega} \|y - y(u_\ell)\|_{1,\Omega},$$

and hence,

$$(5.4) \quad \|y - y(u_\ell)\|_{1,\Omega} \leq M \|e_u\|_{0,\Omega}.$$

Likewise, choosing $v = \bar{p} - \bar{p}(y_\ell)$ in (2.8) and (4.8b), for the first term on the right-hand side in (5.3b) it follows that

$$\|\bar{p} - \bar{p}(y_\ell)\|_{1,\Omega}^2 \leq M \|e_y\|_{0,\Omega} \|\bar{p} - \bar{p}(y_\ell)\|_{0,\Omega} \leq M \|e_y\|_{1,\Omega} \|\bar{p} - \bar{p}(y_\ell)\|_{1,\Omega}.$$

Consequently, in view of (5.3a) and (5.4) we obtain

$$(5.5) \quad \|\bar{p} - \bar{p}(y_\ell)\|_{1,\Omega} \leq M \|e_y\|_{1,\Omega} \leq M^2 \|e_u\|_{0,\Omega} + M \|y(u_\ell) - y_\ell\|_{1,\Omega}.$$

Using (5.4),(5.5) in (5.3a),(5.3b) gives (5.2). \square

Lemma 5.3. Under the same assumptions as in Lemma 5.2 there holds

$$(5.6) \quad \begin{aligned} \|e_u\|_{0,\Omega}^2 &\leq \frac{3}{\alpha^2} \left(M^2 \|y(u_\ell) - y_\ell\|_{1,\Omega}^2 + \|\bar{p}(y_\ell) - \bar{p}_\ell\|_{1,\Omega}^2 + \right. \\ &\quad \left. + (\tilde{e}_c^{(1)}(\psi, \psi_\ell))^2 + (\tilde{e}_c^{(2)}(u, u_\ell))^2 + \text{osc}_\ell^2(u^d) \right) + \frac{1}{3} \text{osc}_\ell^2(\psi). \end{aligned}$$

Proof. Using (2.6c),(2.9) and (3.3c),(3.6), we find

$$(5.7) \quad \alpha \|e_u\|_{0,\Omega}^2 = (e_u, \bar{p}_\ell - \bar{p})_{0,\Omega} + \varepsilon(e_u, \sigma_\ell - \sigma)_{0,\Omega} + (e_u, \bar{\sigma}_\ell - \bar{\sigma})_{0,\Omega} + \alpha(e_u, u^d - u_\ell^d)_{0,\Omega} .$$

The first term on the right-hand side in (5.7) can be split according to

$$(5.8) \quad (e_u, \bar{p}_\ell - \bar{p})_{0,\Omega} = (e_u, \bar{p}_\ell - \bar{p}(y_\ell))_{0,\Omega} + (e_u, \bar{p}(y_\ell) - \bar{p})_{0,\Omega} .$$

An application of Young's inequality yields

$$(5.9) \quad (e_u, \bar{p}_\ell - \bar{p}(y_\ell))_{0,\Omega} \leq \frac{\alpha}{12} \|e_u\|_{0,\Omega}^2 + \frac{3}{\alpha} \|\bar{p}_\ell - \bar{p}(y_\ell)\|_{0,\Omega}^2 .$$

On the other hand, choosing $v = \bar{p} - \bar{p}(y_\ell)$ in (2.6a),(4.8a) and $v = y - y(u_\ell)$ in (2.8),(4.8b), for the second term on the right-hand side in (5.8) we get

$$(5.10) \quad \begin{aligned} (e_u, \bar{p}(y_\ell) - \bar{p})_{0,\Omega} &= -(y - y_\ell, y - y(u_\ell))_{0,\Omega} = \\ &= -\|y - y(u_\ell)\|_{0,\Omega}^2 + (y_\ell - y(u_\ell), y - y(u_\ell))_{0,\Omega} \leq \\ &\leq \|y - y(u_\ell)\|_{1,\Omega} \|y(u_\ell) - y_\ell\|_{1,\Omega} \leq \\ &\leq \frac{\alpha}{12} \|e_u\|_{0,\Omega}^2 + \frac{3M^2}{\alpha} \|y(u_\ell) - y_\ell\|_{1,\Omega}^2 , \end{aligned}$$

where we have further made use of (5.4) and of Young's inequality in the last estimate. Using (5.9) and (5.10) in (5.8) results in

$$(5.11) \quad \begin{aligned} (e_u, \bar{p}_\ell - \bar{p}(y_\ell))_{0,\Omega} &\leq \\ &\leq \frac{\alpha}{6} \|e_u\|_{0,\Omega}^2 + \frac{3}{\alpha} \left(\|\bar{p}_\ell - \bar{p}(y_\ell)\|_{1,\Omega}^2 + M^2 \|y(u_\ell) - y_\ell\|_{1,\Omega}^2 \right) . \end{aligned}$$

As far as the third term on the right-hand side in (5.7) is concerned, in view of (2.6a), (3.3a), (4.8a), (4.9), (2.7) and (3.4) we obtain

$$(5.12) \quad \begin{aligned} (e_u, \bar{\sigma}_\ell - \bar{\sigma})_{0,\Omega} &= \\ &= (\nabla(y_\ell(u) - y_\ell), \nabla \bar{\sigma}_\ell)_{0,\Omega} + (c(y_\ell(u) - y_\ell), \bar{\sigma}_\ell)_{0,\Omega} - \\ &\quad - (\nabla(y - y(u_\ell)), \nabla \bar{\sigma})_{0,\Omega} - (c(y - y(u_\ell)), \bar{\sigma})_{0,\Omega} = \\ &= (\sigma_\ell, y_\ell(u) - y_\ell)_{0,\Omega} + (\sigma, y(u_\ell) - y)_{0,\Omega} . \end{aligned}$$

Combining (5.12) with the second term on the right-hand side in (5.7) and using the complementarity conditions (2.6d) and (3.3d) as well as

(4.11a) and (4.11b), we find

$$\begin{aligned}
& \varepsilon(e_u, \sigma_\ell - \sigma)_{0,\Omega} + (e_u, \bar{\sigma}_\ell - \bar{\sigma})_{0,\Omega} = (\sigma_\ell, \varepsilon u + y_\ell(u) - (\varepsilon u_\ell + y_\ell))_{0,\Omega} \\
& - (\sigma, \varepsilon u + y - (\varepsilon u_\ell + y(u_\ell)))_{0,\Omega} = (\sigma_\ell, \varepsilon u + y_\ell(u) - \psi)_{0,\Omega} \\
& + (\sigma, \varepsilon u_\ell + y(u_\ell) - \psi_\ell)_{0,\Omega} + (\sigma_\ell - \sigma, \psi - \psi_\ell)_{0,\Omega} \\
& + \underbrace{(\sigma_\ell, \psi_\ell - (\varepsilon u_\ell + y_\ell))_{0,\Omega}}_{=0} - \underbrace{(\sigma, \varepsilon u + y - \psi)_{0,\Omega}}_{=0} \\
& \leq \|u - u_\ell\|_{0,\Omega} \tilde{e}_c^{(2)}(u, u_\ell) + \|\psi - \psi_\ell\|_{0,\Omega} \tilde{e}_c^{(1)}(\psi, \psi_\ell),
\end{aligned}$$

whence by Young's inequality

$$\begin{aligned}
(5.13) \quad & \varepsilon(e_u, \sigma_\ell - \sigma)_{0,\Omega} + (e_u, \bar{\sigma}_\ell - \bar{\sigma})_{0,\Omega} \leq \\
& \leq \frac{\alpha}{6} \left(\|e_u\|_{0,\Omega}^2 + \text{osc}_\ell^2(\psi) \right) + \frac{3}{2\alpha} \left((\tilde{e}_c^{(1)}(\psi, \psi_\ell))^2 + (\tilde{e}_c^{(2)}(u, u_\ell))^2 \right).
\end{aligned}$$

Finally, another application of Young's inequality gives us the following upper bound for the fourth term on the right-hand side in (5.7)

$$(5.14) \quad \alpha(e_u, u^d - u_\ell^d)_{0,\Omega} \leq \frac{\alpha}{6} \|e_u\|_{0,\Omega}^2 + \frac{3}{2\alpha} \text{osc}_\ell^2(u^d).$$

Taking advantage of the estimates (5.11),(5.13),(5.14) in (5.7) allows to conclude. \square

Lemma 5.4. Under the same assumptions as in Lemma 5.2 there holds

$$(5.15a) \quad \|y(u_\ell) - y_\ell\|_{1,\Omega} \lesssim \eta_y,$$

$$(5.15b) \quad \|\bar{p}(y_\ell) - \bar{p}_\ell\|_{1,\Omega} \lesssim \eta_{\bar{p}}.$$

Proof. Due to Galerkin orthogonality, the assertion follows by standard arguments from the a posteriori error analysis of adaptive finite element methods (see, e.g., [41]). \square

Proof of Theorem 5.1. Combining the estimates from Lemma 5.2, Lemma 5.3, and Lemma 5.4 results in (5.1).

6. LOCAL EFFICIENCY OF THE ERROR ESTIMATOR

Efficiency of the estimator means that up to data oscillations it also provides a lower bound for the discretization errors in the state, the regularized adjoint state, and the control.

Theorem 6.1. *Let (y, u, p, σ) and $(y_\ell, u_\ell, p_\ell, \sigma_\ell)$ be the solutions of (2.6a)-(2.6d) and (3.3a)-(3.3d) and let η_ℓ and $\text{osc}_\ell(y^d)$ be the error*

estimator and the data oscillation as given by (4.1) and (4.6b), respectively. Further, let \bar{p} and \bar{p}_ℓ be the modified adjoint states as given by (2.8),(3.5). Then, there holds

$$(6.1) \quad \eta_\ell - \text{osc}_\ell(y^d) \lesssim \|e_y\|_{1,\Omega} + \|e_u\|_{0,\Omega} + \|e_{\bar{p}}\|_{1,\Omega}.$$

The proof of the efficiency of the estimator is usually done by establishing local efficiency in the sense that the element and edge residuals can be bounded from above by norms of the discretization errors on the elements and associated patches, respectively. Local efficiency will be provided by the subsequent two lemmas.

Lemma 6.2. Let $\eta_T(y)$ and $\eta_T(\bar{p})$, $T \in \mathcal{T}_\ell(\Omega)$, be the element residuals as given by (4.3). Then, there holds

$$(6.2) \quad \eta_T^2(y) \lesssim \|e_y\|_{1,T}^2 + h_T^2 \|e_u\|_{0,T}^2,$$

$$(6.3) \quad \eta_T^2(\bar{p}) \lesssim \|e_{\bar{p}}\|_{1,T}^2 + h_T^2 \|e_y\|_{0,T}^2 + \text{osc}_T^2(y^d).$$

Proof. We denote by $\varphi_T = \prod_{i=1}^3 \lambda_i(T)$ the element bubble function associated with $T \in \mathcal{T}_\ell(\Omega)$ (cf., e.g., [41]). Then, $\xi_\ell := (u_\ell - cy_\ell)\varphi_T$ is an admissible test function in (2.6a). Observing $\Delta y_\ell|_T = 0$, we obtain

$$\begin{aligned} \eta_T^2(y) &\lesssim h_T^2 (u_\ell - cy_\ell, \xi_\ell)_{0,T} = \\ &= h_T^2 \left((u, \xi_\ell)_{0,T} + (\Delta y_\ell - cy_\ell, \xi_\ell)_{0,T} + (u_\ell - u, \xi_\ell)_{0,T} \right) = \\ &= h_T^2 \left((\nabla(y - y_\ell), \nabla \xi_\ell)_{0,T} + (c(y - y_\ell), \xi_\ell)_{0,T} + (u_\ell - u, \xi_\ell)_{0,T} \right). \end{aligned}$$

Using standard estimates for $\|\nabla \xi_\ell\|_{0,T}$ and $\|\xi_\ell\|_{0,T}$ (cf., e.g., [41]) readily gives (6.2). The estimate (6.3) can be verified in the same way. \square

Lemma 6.3. Let $\eta_T(y)$, $\eta_T(\bar{p})$, $T \in \mathcal{T}_\ell(\Omega)$, and $\eta_E(y)$, $\eta_E(\bar{p})$, $E \in \mathcal{E}_\ell(\Omega)$, be the element and edge residuals as given by (4.3),(4.4). Further, let $\text{osc}_T(y^d)$, $T \in \mathcal{T}_\ell(\Omega)$, be the element contribution to the data oscillation in y^d according to (4.6b). Then, there holds

$$(6.4) \quad \eta_E^2(y) \lesssim \|e_y\|_{1,\omega_E}^2 + h_E^2 \|e_u\|_{0,\omega_E}^2 + \eta_{\omega_E}^2(y),$$

$$(6.5) \quad \eta_E^2(\bar{p}) \lesssim \|e_{\bar{p}}\|_{1,\omega_E}^2 + h_E^2 \|e_y\|_{0,\omega_E}^2 + \eta_{\omega_E}^2(\bar{p}) + \text{osc}_{\omega_E}^2(y^d),$$

where $\eta_{\omega_E}(y) := (\eta_{T_+}^2(y) + \eta_{T_-}^2(y))^{1/2}$ and $\eta_{\omega_E}(\bar{p})$, $\text{osc}_{\omega_E}(y^d)$ are defined analogously.

Proof. We denote by $\varphi_E = \prod_{i=1}^2 \lambda_i(E)$, the edge bubble function associated with $E \in \mathcal{E}_\ell(\Omega)$ (cf., e.g., [41]). We set $\zeta_E := (\nu_E \cdot [\nabla y_\ell])|_E$ and $\xi_\ell := \tilde{\zeta}_E \varphi_E$, where $\tilde{\zeta}_E$ is the extension of ζ_E to ω_E as in [41]. Taking

advantage of the fact that ξ_ℓ is an admissible test function in (2.6a) and $\Delta y_\ell|_T = 0$, it follows that

$$\begin{aligned} \eta_E^2(y) &\lesssim h_E(\nu_E \cdot [\nabla y_\ell], \zeta_E \varphi_E)_{0,E} = \\ &= h_E \sum_{T \subset \omega_E} \left((\nu_{\partial T} \cdot \nabla y_\ell, \xi_\ell)_{0,\partial T} - (\Delta y_\ell, \xi_\ell)_{0,T} \right) = \\ &= h_E \left((\nabla(y_\ell - y), \nabla \xi_\ell)_{0,\omega_E} + (c(y_\ell - y), \xi_\ell)_{0,\omega_E} + \right. \\ &\quad \left. (u - u_\ell, \xi_\ell)_{0,\omega_E} + (u_\ell - cy_\ell, \xi_\ell)_{0,\omega_E} \right). \end{aligned}$$

Standard estimates for ξ_ℓ (cf., e.g., [41]) readily give (6.4). The estimate (6.5) can be proved along the same lines. \square

Proof of Theorem 6.1. The efficiency estimate (6.1) follows by summing up the estimates (6.3)-(6.5) over all $T \in \mathcal{T}_\ell(\Omega)$ and $E \in \mathcal{E}_\ell(\Omega)$. Using the fact that the union of the patches ω_E has a finite overlap allows to conclude.

7. NUMERICAL RESULTS

In this section, we illustrate the approximation of state constrained optimal control problems by its Lavrentiev type regularizations using two numerical examples representing two different instances of the possible structure of the Lagrange multiplier according to the classification by Bergounioux and Kunisch [8]. The first example features a solution y that strongly oscillates around the origin where the coincidence set is a connected subdomain with smooth boundary. In contrast to that, the second example, which is taken from [32], features a multiplier in $\mathcal{M}_+(\Omega)$ where the coincidence set degenerates to a single point. In both cases the adaptive process generates finite element meshes that are close to those created when one uses the adaptive strategy for state constrained problems as suggested in [26].

Example 1 (Simply connected coincidence set with smooth boundary): The data of the problem are as follows

$$\begin{aligned} \Omega &:= (-2, 2)^2, \quad \psi := 0, \quad \alpha := 0.1, \quad c = 0, \quad \Gamma_D := \partial\Omega, \\ y^d &:= y(r) + \Delta p(r) + \sigma(r), \quad u^d := u(r) + \alpha^{-1} p(r). \end{aligned}$$

Here, $y = y(r)$, $u = u(r)$, $p = p(r)$ and $\sigma = \sigma(r)$, $r := (x_1^2 + x_2^2)^{1/2}$, $(x_1, x_2)^T \in \Omega$, represent the exact optimal solution of the pure state

constrained problem ($\varepsilon = 0$) according to

$$\begin{aligned} y(r) &:= -r^{\frac{4}{3}} \gamma_1(r) & , & & u(r) &:= -\Delta y(r) , \\ p(r) &:= \gamma_2(r) \left(r^4 - \frac{3}{2}r^3 + \frac{9}{16}r^2 \right) & , & & \sigma(r) &:= \begin{cases} 0 , & r < 0.75 \\ 0.1 , & \text{otherwise} \end{cases} , \end{aligned}$$

where

$$\begin{aligned} \gamma_1 &:= \begin{cases} 1, & r < 0.25 \\ -192(r - 0.25)^5 + 240(r - 0.25)^4 - \\ -80(r - 0.25)^3 + 1, & 0.25 < r < 0.75 \\ 0, & \text{otherwise} \end{cases} , \\ \gamma_2 &:= \begin{cases} 1 , & r < 0.75 \\ 0 , & \text{otherwise} \end{cases} . \end{aligned}$$

Figure 1 shows the computed optimal state y_ℓ and optimal control u_ℓ in case of an adaptively generated simplicial triangulation with 9194 degrees of freedom and $\varepsilon = 10^{-6}$, whereas Figure 2 displays the adaptively generated meshes after 12 (left) and 14 (right) refinement steps for $\varepsilon = 10^{-6}$.

FIGURE 1. Example 1: Visualization of the discrete optimal state y_ℓ (left) and the discrete optimal control u_ℓ (right) on a triangulation with 9194 nodes and with regularization parameter $\varepsilon = 10^{-6}$

Table 1 documents the convergence history of the adaptive refinement process with respect to the convergence of the solutions of the discrete mixed control-state problems ($\varepsilon = 10^{-6}$) to the exact solution of the pure state constrained problem. We remark that the impact of the regularization parameter ε has to be observed in the error estimates. In particular, Table 1 contains the H^1 -error in the state, the L^2 -errors in the control and in the adjoint state as well as the H^1 -error

FIGURE 2. Example 1: Adaptively generated grid after 12 (left) and 14 (right) refinement steps, $\Theta_i = 0.7$, $\epsilon = 10^{-6}$

in the regularized adjoint state. The adaptive refinement process has been terminated when the size of the regularization parameter $\epsilon = 10^{-6}$

started to blur the results. The same effect could be observed for larger values of ε (see also Figure 3 (right)). For a comparison, Table 2 shows the decrease of the discretization errors in the limiting case $\varepsilon = 0$ (pure state constraints). We observe that in this example the most significant impact of the regularization parameter is on the errors in the adjoint state and the regularized adjoint state.

Figure 3 (left) illustrates the benefit of adaptive versus uniform refinement by showing on a logarithmic scale the error in the control as a function of the degrees of freedom ($\varepsilon = 10^{-6}$). Figure 3 (right) contains a comparison of the error in the control for the pure state constrained problem ($\varepsilon = 0$) and its Lavrentiev regularizations ($\varepsilon = 10^{-2}, 10^{-4}, 10^{-6}$).

FIGURE 3. Example 1: Adaptive refinement [straight line] versus uniform refinement [dotted line] (left) and discretization error in the control for different regularization parameters (right)

The residual-type estimators $\eta_\ell(y)$ in the state and $\eta_\ell(\bar{p})$ in the regularized adjoint state as well as the data oscillations $osc_\ell(u^d)$ in the shift control and $osc_\ell(y^d)$ in the desired state are given in Table 3. Again, for a comparison with the pure state constrained case, Table 4 contains the corresponding values in case $\varepsilon = 0$.

Example 2 (Degenerated coincidence set [32]): The data of the problem are as follows

$$\begin{aligned} \Omega &:= B(0,1) \quad , \quad \Gamma_D = \emptyset \quad , \quad \alpha := 1.0 \quad , \quad c = 1.0 \quad , \\ y^d(r) &:= 4 + \frac{1}{\pi} - \frac{1}{4\pi}r^2 + \frac{1}{2\pi}\ln(r) \quad , \\ u^d(r) &:= 4 + \frac{1}{4\pi}r^2 - \frac{1}{2\pi}\ln(r) \quad , \quad \psi(r) := r + 4 \quad . \end{aligned}$$

The optimal solution in the pure state constrained case is given by:

$$\begin{aligned} y(r) &\equiv 4 \quad , \quad p(r) = \frac{1}{4\pi}r^2 - \frac{1}{2\pi}\ln(r) \quad , \\ u(r) &\equiv 4 \quad , \quad \sigma = \delta_0 \quad . \end{aligned}$$

Figure 4 displays the computed optimal state y_ℓ and optimal control u_ℓ for a simplicial triangulation with 964 degrees of freedom. For the regularization parameter $\epsilon = 10^{-6}$, the adaptively generated grids after 12 and 14 refinement steps are shown in Figure 5.

FIGURE 4. Example 2: Visualization of the discrete state y_l (left) and the discrete control u_l (right) on an adaptive generated mesh with 964 nodes and with regularization parameter $\epsilon = 10^{-6}$

FIGURE 5. Example 2: Adaptively generated grid after 12 (left) and 14 (right) refinement steps, $\Theta_i = 0.7$, $\epsilon = 10^{-6}$

In case $\epsilon = 10^{-6}$, Table 5 and Table 7 reflect the convergence history of the adaptive refinement process with data analogous to those in Example 1. As before, in order to compare with the pure state constrained case ($\epsilon = 0$), the associated data are given in Table 6 and Table 8. We remark that there are no data oscillations in ψ in the pure state constrained case $\epsilon = 0$, since $\langle \sigma - \sigma_\ell, \psi - \psi_\ell \rangle = 0$ where $\langle \cdot, \cdot \rangle$ stands for the dual pairing between the space of Radon measures and the space of continuous functions (cf. [26]). We see that here the impact of the regularization parameter is less pronounced than in the first example (provided ϵ is chosen sufficiently small; see also Figure 6 (right)). The benefit of adaptive versus uniform refinement is addressed in Figure 6 (left) which displays on a logarithmic scale the discretization error in
