Alternative constructions of a harmonic function for a random walk in a cone

Denis Denisov*  
Vitali Wachteli†

Abstract
For a random walk killed at leaving a cone we suggest two new constructions of a positive harmonic function. These constructions allow one to remove a quite strong extendability assumption, which has been imposed in our previous paper (Denisov and Wachtel, 2015, Random walks in cones). As a consequence, all the limit results from that paper remain true for cones which are either convex or star-like and $C^2$.

Keywords: random walk; exit time; harmonic function.

AMS MSC 2010: Primary 60G50, Secondary 60G40; 60F17.

1 Introduction and the main result
Consider a random walk \{\(S(n), n \geq 1\)\} on \(\mathbb{R}^d, d \geq 1\), where
\[
S(n) = X(1) + \cdots + X(n)
\]
and \{\(X(n), n \geq 1\)\} is a family of independent copies of a random vector \(X = (X_1, X_2, \ldots, X_d)\). We will assume that the random variables have zero mean, unit variance, and are uncorrelated, that is \(E[X_i] = 0\), \(\text{Var}(X_i) = 1\) for \(1 \leq i \leq d\) and \(\text{cov}(X_i, X_j) = 0\) for \(1 \leq i < j \leq d\).

Denote by \(S^{d-1}\) the unit sphere of \(\mathbb{R}^d\) and \(\Sigma\) an open and connected subset of \(S^{d-1}\). Let \(K\) be the cone generated by the rays emanating from the origin and passing through \(\Sigma\), i.e. \(\Sigma = K \cap S^{d-1}\). Let \(\tau_x\) be the exit time from \(K\) of the random walk with starting point \(x \in K\), that is,
\[
\tau_x = \inf\{n \geq 1 : x + S(n) \notin K\}.
\]
In the present paper we are concerned with the existence of a positive harmonic function \(V\) for a random walk killed at the exit from \(K\), that is a function \(V\) which solves the following equation
\[
E[V(x + X), \tau_x > 1] = V(x), \quad x \in K.
\]

Harmonic function $V(x)$ plays a central role in our approach to study of the Markov processes confined to unbounded domains. This approach was initiated in [8], where we studied random walks in a Weyl chamber, which is an example of a cone. These studies were extended in [9], where we considered random walks in general cones. In particular, in [9] we showed that
\begin{equation*}
\mathbb{P}(\tau_x > n) \sim CV(x)^{n/p/2}, \quad n \to \infty,
\end{equation*}
and proved global and local limit theorems for random walks conditioned on $\{\tau_x > n\}$. The approach suggested in [9] was further extended to one-dimensional random walks above the curved boundaries [11], [6], [7], integrated random walks [10], [5], products of random matrices [14], and Markov walks [13].

This approach is based on the universality ideas and heavily relies on corresponding results for Brownian motion, or, more generally, diffusion processes. Thus, an important role is played by the harmonic function of the Brownian motion killed at the boundary of $K$, which can be described as the minimal (up to a constant), strictly positive on $K$ solution of the following boundary problem:
\begin{equation*}
\Delta u(x) = 0, \quad x \in K \quad \text{with boundary condition} \quad u|_{\partial K} = 0.
\end{equation*}

The function $u(x)$ and constant $p$ can be found as follows. If $d = 1$ then we have only one non-trivial cone $K = (0, \infty)$. In this case $u(x) = x$ and $p = 1$. Assume now that $d \geq 2$. Let $L_{S^{d-1}}$ be the Laplace-Beltrami operator on $S^{d-1}$ and assume that $\Sigma$ is regular with respect to $L_{S^{d-1}}$. With this assumption, there exists a complete set of orthonormal eigenfunctions $m_j$ and corresponding eigenvalues $0 < \lambda_1 < \lambda_2 \leq \lambda_3 \leq \ldots$ satisfying
\begin{align*}
L_{S^{d-1}}m_j(x) &= -\lambda_j m_j(x), \quad x \in \Sigma \\
m_j(x) &= 0, \quad x \in \partial \Sigma. \quad (1.1)
\end{align*}

Then
\begin{equation*}
p = \sqrt{\lambda_1 + (d/2 - 1)^2} - (d/2 - 1) > 0,
\end{equation*}
and the harmonic function $u(x)$ of the Brownian motion is given by
\begin{equation*}
u(x) = |x|^p m_1 \left(\frac{x}{|x|}\right), \quad x \in K. \quad (1.2)
\end{equation*}

We refer to [2] for further details on exit times of Brownian motion. For symmetric stable Lévy processes asymptotics for exit times and related questions have been considered in [1], [3] and [15], see also references therein.

In [9] we showed that one construct a harmonic function for the random walk killed at $\tau_x$ as follows
\begin{equation*}
V(x) = \lim_{n \to \infty} \mathbb{E}[u(x + S(n), \tau_x > n)].
\end{equation*}

The existence and positivity of $V$ was shown under certain assumptions. The geometric assumptions in [9] can be summarised as follows,

(i) $K$ is either starlike with $\Sigma$ in $C^2$ or convex. We say that $K$ is starlike if there exists $x_0 \in \Sigma$ such that $x_0 + K \subset K$ and $\text{dist}(x_0 + K, \partial K) > 0$. Clearly, every convex cone is also starlike, for the proof see Remark 15 in [9].

(ii) We assume that there exists an open and connected set $\hat{\Sigma} \subset S^{d-1}$ with $\text{dist}(\partial \Sigma, \partial \hat{\Sigma}) > 0$ such that $\Sigma \subset \hat{\Sigma}$ and the function $m_1$ can be extended to $\hat{\Sigma}$ as a solution to (1.1).
Assumption (ii) is quite restrictive. For this assumption to hold it is necessary to assume that the boundary of the cone is piecewise infinitely differentiable. But this condition is not sufficient. The restriction (ii) excludes many cones which are of interest in various mathematical problems. For example, it is not clear whether (ii) holds for linear transformations of the orthant \( \mathbb{R}^d_+ \), \( d \geq 2 \) which appear often in paths enumeration problems in combinatorics. (It is worth mentioning that (ii) holds for any simply connected open cone in \( \mathbb{R}^2 \). This follows from the observation that \( m_1(x) = \sin(C_1 + C_2x) \) in this two-dimensional situation.)

We have shown in [9] that the condition (ii) can be dropped in the case when the random walk \( \{S(n)\} \) has bounded jumps, Raschel and Tarrago [17] have recently shown that (ii) can be removed under stronger than in [9] moment restrictions on the vector \( X \). The main aim of this paper is to show that this assumption can be removed without imposing any further conditions. Namely, we prove that (i) is sufficient and the following result holds.

**Theorem 1.1.** Assume that either the cone \( K \) is convex or \( \Sigma \) is \( C^2 \) and \( K \) is starlike. If \( E|X|^\alpha \) is finite for \( \alpha = p \) if \( p > 2 \) or for some \( \alpha > 2 \) if \( p \leq 2 \), then the function

\[
V(x) := \lim_{n \to \infty} E[u(x + S(n)); \tau_x > n]
\]

is finite and harmonic for \( \{S(n)\} \) killed at leaving \( K \), i.e.,

\[
V(x) = E[V(x + S(n)); \tau_x > n], \quad x \in K, \ n \geq 1.
\]

Furthermore, \( V(x) \) is strictly positive on the set

\[
K_+ := \{ x \in K : \text{there exists } \gamma > 0 \text{ such that for every } R > 0 \ \
\text{there exists } n \text{ such that } P(x + S(n) \in D_{R, \gamma}, \tau_x > n) > 0 \},
\]

where \( D_{R, \gamma} := \{ x \in K : |x| \geq R, \text{dist}(x, \partial K) \geq \gamma|x| \} \).

We will present two very different proofs of this theorem. The first proof uses preliminary bounds for the moments of exit times of \( \tau_x \) due to [16], see Lemma 2.6 below. The proof is similar to that in [9], but we use an additional idea of time-dependent shifts inside the cone. Thus the approach is reminiscent of one-dimensional random walks conditioned to stay above curved boundaries [6].

The second proof combines time-dependent shifts with an iterative procedure similar to that in [8] and [10]. The main advantage of this approach is that in principle no preliminary information on moments of exit times is needed. However, we use [16] to obtain optimal moment conditions. If we assume two additional moments then this approach becomes self-contained, see Remark 5.4 below.

A further advantage of new constructions consists in the fact that we do not use estimates for the concentration function of the random walk \( \{S(n)\} \), which were important for the method used in [9].

Since the geometric assumption (ii) has been used in [9] in the construction of \( V(x) \) only, Theorem 1.1 allows us to state limit theorems for random walks in cones proven in [9] and in [12] for all cones satisfying (i).

**Corollary 1.2.** Under the conditions of Theorem 1.1, as \( n \to \infty \),

\[
P(\tau_x > n) \sim x^V(x)n^{-p/2},
\]

\[
P\left( \frac{x + S(n)}{\sqrt{n}} \in \cdot \ | \tau_x > n \right) \Rightarrow \mu \quad \text{weakly},
\]

where \( \mu \) is a probability measure on \( K \) with the density \( H_0u(y)e^{-|y|^2/2} \). Furthermore, the process \( \left\{ \frac{x + S([nt])}{\sqrt{n}}, \ t \in [0, 1] \right\} \) conditioned on \( \{\tau_x > n\} \) converges weakly in the space \( D([0, 1], \| \cdot \|_\infty) \).
Corollary 1.3. Assume that $X$ takes values on a lattice $R$ which is a non-degenerate linear transformation of $\mathbb{Z}^d$. Then, under the assumptions of Theorem 1.1,

$$\sup_{y \in D_n(x)} |r^{p/2+d/2} P(x + S(n) = y, \tau > n) - C_0 V(x) u \left( \frac{y}{\sqrt{n}} \right) e^{-|y|^2/2n}| \to 0,$$

where

$$D_n(x) := \{ y \in K : P(x + S(n) = y) > 0 \}.$$

The constant $C_0$ is a product of the volume of the unit cell in $R$ and of a factor, which depends on the periodicity of the distribution of $X$.

In the proof of Theorem 5 in [9] we have required the strong aperiodicity of $X$. This has been done to use the simplest version of the local limit theorem for unrestricted random walks from Spitzer’s book [18]. But this standard result can be replaced by Stone’s local limit theorem which is valid for all lattice walks, see [19].

2 Preliminary estimates

We first collect some useful facts about the classical harmonic function $u(x)$.

Lemma 2.1. There exists a constant $C = C(d)$ such that for $x \in K$

$$|\nabla u(x)| \leq C \frac{u(x)}{\text{dist}(x, \partial K)},$$

$$|u_x| \leq C \frac{u(x)}{\text{dist}(x, \partial K)},$$

$$|u_{x,j}| \leq C \frac{u(x)}{\text{dist}(x, \partial K)^2},$$

$$|u_{x,i,j}| \leq C \frac{u(x)}{\text{dist}(x, \partial K)^3}. \quad (2.1)$$

Proof. Recalling that every partial derivative $u_{x,i}$ is harmonic and using the mean value theorem for harmonic functions, we obtain

$$u_{x,i}(x) = \frac{1}{\text{Vol}(B(x,r))} \int_{B(x,r)} u_{x,i}(y) dy,$$

where $B(x, r)$ is the ball of radius $r$ around $x$ and $r < \text{dist}(x, \partial K)$. By the Gauss-Green theorem,

$$u_{x,i}(x) = \frac{1}{\text{Vol}(B(x,r))} \int_{\partial B(x,r)} u(z) (\nu(z), e_i) dz,$$

where $\nu(z)$ is the outer normal at $z$. Choosing $r = \text{dist}(x, \partial K)/2$ and applying the Harnack inequality in the ball $B(x, \text{dist}(x, \partial K))$, we conclude that

$$|u_{x,i}(x)| \leq 3 \cdot 2^{d-2} \frac{\text{Vol}(\partial B(x,r))}{\text{Vol}(B(x,r))} u(x) = 3d \cdot 2^{d-1} \frac{u(x)}{\text{dist}(x, \partial K)}.\]$$

This implies the desired estimate for $u_{x,i}(x)$. Since $u_{x,j}$ is harmonic as well we can write

$$|u_{x,i,j}| = \left| \frac{1}{\text{Vol}(B(x,r))} \int_{\partial B(x,r)} u_{x,i}(z) (\nu(z), e_j) dz \right| \leq \frac{C(d)}{\text{Vol}(B(x,r)) \text{dist}(x, \partial K)} \int_{\partial B(x,r)} u(z) |(\nu(z), e_j)| dz \leq C(d)^2 \frac{u(x)}{\text{dist}(x, \partial K)^2}.$$

The inequality for the third derivative can be proved analogously. The inequality for the gradient immediately follows from the inequality for the first derivative. $\square$

Alternative constructions of a harmonic function in a cone

For every cone $K$ one has the bound
$$\text{dist}(x, \partial K) \leq |x|, \quad x \in K.$$ Furthermore, it follows from (1.2) that
$$u(x) \leq C|x|^p, \quad x \in K.$$ In the next lemma we derive more accurate estimates for $u(x)$.

**Lemma 2.2.** Assume that either the cone $K$ is convex or $\Sigma$ is $C^2$ and $K$ is starlike. Then
$$C_1 (\text{dist}(x, \partial K))^p \leq u(x) \leq C_2 |x|^{p-1} \text{dist}(x, \partial K), \quad x \in K$$ (2.2)
and
$$|\nabla u(x)| \leq C_3 |x|^{p-1}, \quad x \in K.$$ (2.3)

**Proof.** The upper bound in (2.2) is (0.2.3) in Varopoulos [20] and the lower bound has been proved in Lemma 19 in [9]. Combining the upper bound in (2.2) with Lemma 2.1, we obtain (2.3). $\square$

We will extend the function $u$ by putting $u(x) = 0$ for $x \notin K$.

**Lemma 2.3.** Assume that either the cone $K$ is convex or $\Sigma$ is $C^2$ and $K$ is starlike. Let $x \in K$. Then,
$$|u(x + y) - u(x)| \leq C|y| \left( (|x|^{p-1} + |y|^{p-1}) \right)$$ (2.4)
and, for $|y| \leq |x|/2$,
$$|u(x + y) - u(x)| \leq C|y||x|^{p-1}. \quad (2.5)$$ For $p < 1$ and $x \in K$,
$$|u(x + y) - u(x)| \leq C|y|^p. \quad (2.6)$$

**Proof.** Consider first the case $p \geq 1$. To prove (2.4) consider first the case when the interval $[x, x + y]$ lies in $K$. Then,
$$|u(x + y) - u(x)| = \left| \int_0^1 (\nabla u(x + ty), y) dt \right| \leq |y| \int_0^1 |\nabla u(x + ty)| |t| dt.$$ Hence, by (2.3),
$$|u(x + y) - u(x)| \leq C_3 |y| \int_0^1 |x + ty|^{p-1} dt \leq C_2^{p-1}|y|( |x|^{p-1} + |y|^{p-1}),$$ as required. Now if $[x, x + y]$ does not belong to $K$ then we have two cases: $x + y \in K$ or $x + y \notin K$. If $x + y \in K$ then there exist $t_1, t_2 : 0 < t_1 < t_2 < 1$ such that $[x, x + t_1 y] \subset K$ and $(x + t_2 y, x + y] \subset K$ and $x + t_1 y, x + t_2 y \in \partial K$. If $x + y \notin K$ then there exists $t_1 : 0 < t_1$ such that $[x, x + t_1 y] \subset K$ and we put $t_2 = 1$. Since in both cases $x + t_1 y, x + t_2 y \notin K$ and $u = 0$ outside of $K$ we obtain
$$|u(x) - u(x + y)| = |u(x) - u(x + t_1 y) + u(x + t_2 y) - u(x + y)| \leq |u(x) - u(x + t_1 y)| + |u(x + t_2 y) - u(x + y)|$$
$$= \left| \int_0^{t_1} (\nabla u(x + ty), y) dt \right| + \left| \int_{t_2}^1 (\nabla u(x + ty), y) dt \right|$$
(by (2.3)) \leq C_4 |y| \left( \int_0^{t_1} + \int_{t_2}^1 \right) |x + ty|^{p-1} dt \leq C|y|( |x|^{p-1} + |y|^{p-1}),$$
as required. If \( p \geq 1 \) then (2.5) is immediate from (2.4).

For \( p < 1 \) we will prove a stronger statement (2.6) which clearly implies (2.4). Consider first again the case when the interval \([x, x + y]\) lies in \( K \). If \( |x| \geq 2|y| \) then

\[
|u(x + y) - u(x)| \leq |y| \int_0^1 |\nabla u(x + ty)| dt
\]

\[
\leq C|y| \int_0^1 |x + ty|^{p-1} dt \leq C|y|(2|y| - |y|)^{p-1} \leq C|y|^p
\]

and

\[
|u(x + y) - u(x)| \leq |y| \int_0^1 |\nabla u(x + ty)| dt
\]

\[
\leq C|y| \int_0^1 |x + ty|^{p-1} dt \leq C|y|(|x| - |x|/2)^{p-1} \leq C|y||x|^{p-1}.
\]

Therefore, we have (2.5) and (2.6) for \( |y| \leq |x|/2 \). Furthermore, for \( |x| < 2|y| \) one has

\[
|u(x + y) - u(x)| \leq C(|x| + |y|^p + |y|^p) \leq C(3^p + 1)|y|^p,
\]

which completes the proof (2.6) in the case when \([x, x + y] \subset K \). The case when \([x, x + y]\) does not belong to \( K \) can be considered in the same way as for \( p \geq 1 \). \( \Box \)

For \( x \in K \) let

\[
f(x) = E[u(x + X)] - u(x). \tag{2.7}
\]

Next we require a bound on \( f(x) \).

**Lemma 2.4.** Let the assumptions of Theorem 1.1 hold and \( f \) be defined by (2.7). Then, for some \( \delta > 0 \),

\[
|f(x)| \leq C \frac{|x|^p}{\text{dist}(x, \partial K)^{2+\delta}} \quad \text{for all } x \in K \text{ with } |x| \geq 1.
\]

Furthermore,

\[
|f(x)| \leq C \quad \text{for all } x \in K \text{ with } |x| \leq 1.
\]

**Proof.** Let \( x \in K \) be such that \( |x| \geq 1 \). Put \( g(x) = \text{dist}(x, \partial K) \), and let \( \eta \in (0, 1) \). Then, for any \( y \in B(0, \eta g(x)) \), the interval \([x, x + y] \subset K \). By the Taylor theorem,

\[
|u(x + y) - u(x) - \nabla u \cdot y - \frac{1}{2} \sum_{i,j} u_{x_i x_j} y_i y_j| \leq R_3(x)|y|^3.
\]

The remainder \( R_3(x) \) can be estimated by Lemma 2.1,

\[
R_3(x) = C_d \max_{z \in B(x, \eta g(x))} \max_{i,j,k} |u_{x_i x_j x_k}| \leq C \frac{(1 + \eta)^p}{(1 - \eta)^3 g(x)^3} |x|^p,
\]

which will give us

\[
|u(x + y) - u(x) - \nabla u \cdot y - \frac{1}{2} \sum_{i,j} u_{x_i x_j} y_i y_j| \leq C \frac{|x|^p}{g(x)^3} |y|^3. \tag{2.8}
\]
Alternative constructions of a harmonic function in a cone

Then we can proceed as follows

\[ |f(x)| = |E (u(x + X) - u(x)) 1(|X| \leq \eta g(x))| + E (u(x + X) - u(x)) 1(|X| > \eta g(x)) \]

\[ \leq E \left[ \left( \nabla u \cdot X + \frac{1}{2} \sum_{i,j} u_{x_i x_j} X_i X_j \right) 1(|X| \leq \eta g(x)) \right] \]

\[ + C |x|^p g(x)^4 E \left[ |X|^3 1(|X| \leq \eta g(x)) \right] \]

\[ + C E \left[ (|x|^p + |X|^p) 1(|X| > \eta g(x)) \right]. \]

Here we used also the bounds \(|u(x + y) - u(x)| \leq C(|x + y|^p + |x|^p) \leq C(|x|^p + |y|^p) valid for all \(x\) and \(y\). After rearranging the terms we obtain

\[ |f(x)| \leq E \left[ \nabla u \cdot X + \frac{1}{2} \sum_{i,j} u_{x_i x_j} X_i X_j \right] \]

\[ + E \left[ \left( \nabla u \cdot X + \frac{1}{2} \sum_{i,j} u_{x_i x_j} X_i X_j \right) 1(|X| > \eta g(x)) \right] \]

\[ + C |x|^p g(x)^4 E \left[ |X|^3 1(|X| \leq \eta g(x)) \right] \]

\[ + C E \left[ (|x|^p + |X|^p) 1(|X| > \eta g(x)) \right]. \]

Now note that the first term is 0 due to \(E X_i = 0\), \(\text{cov}(X_i, X_j) = \delta_{ij}\) and \(\Delta u = 0\). The partial derivatives of the function \(u\) in the second term can be estimated via Lemma 2.1, which results in the following estimate

\[ |f(x)| \leq C \left( \frac{|x|^p}{g(x)} E \left[ |X|; |X| > \eta g(x) \right] + \frac{|x|^p}{g(x)} E \left[ |X|^2; |X| > \eta g(x) \right] \]

\[ + \frac{|x|^p}{g(x)} E \left[ |X|^3; |X| \leq \eta g(x) \right] + |x|^p P(|X| > \eta g(x)) \]

\[ + E \left[ |X|^p; |X| > \eta g(x) \right]. \]

Hence, from the Markov inequality we conclude

\[ |f(x)| \leq C \frac{|x|^p}{\eta^2 g^2(x)} E \left[ |X|^2; |X| > \eta g(x) \right] + C \frac{|x|^p}{g^4(x)} E \left[ |X|^3; |X| \leq \eta g(x) \right] \]

\[ + C E \left[ |X|^p; |X| > \eta g(x) \right]. \quad (2.9) \]

Now recall the moment assumption that \(E|X|^{2+\delta} < \infty\) for some \(\delta > 0\). The first term is estimated via the Chebyshev inequality,

\[ \frac{|x|^p}{\eta^2 g^2(x)} E \left[ |X|^2; |X| > \eta g(x) \right] \leq \frac{|x|^p}{\eta^{2+\delta} g^{2+\delta}(x)} E|X|^{2+\delta}. \]

The second term can be estimated similarly,

\[ \frac{|x|^p}{g^4(x)} E \left[ |X|^3; |X| \leq \eta g(x) \right] \leq \frac{|x|^p}{\eta^{1-\delta} g^{1-\delta}(x)} E|X|^{2+\delta}. \]

In order to bound the last term in (2.9) we have to distinguish between \(p \leq 2\) and \(p > 2\).
Alternative constructions of a harmonic function in a cone

If \( p \leq 2 \), then, by the Chebyshev inequality,

\[
\mathbb{E} [ |X|^p; |X| > \eta g(x) ] \leq \frac{1}{(\eta g(x))^{2+\delta-p}} \mathbb{E} [ |X|^{2+\delta} ] \leq C \frac{|x|^p}{g^{2+\delta}(x)},
\]
as \( g(x) = \text{dist}(x, \partial K) \leq |x| \).

In case \( p > 2 \) we have, according to our moment condition, \( \mathbb{E}[|X|^p] < \infty \). Consequently,

\[
\mathbb{E} [ |X|^p; |X| > \eta g(x) ] \leq C.
\]
The second statement follows easily from the fact that \( u(x) \) is bounded on \( |x| \leq 1 \) and the inequality \( \mathbb{E}[u(x + X)] \leq C(1 + \mathbb{E}[|X|^p]) \).

We derive next an estimate for the maximum

\[
M(n) := \max_{k \leq n} |S(k)|,
\]
which will be used several times in the proofs of our main results.

**Lemma 2.5.** If \( |X|^r < \infty \) for some \( r \geq 2 \) then, uniformly in \( x \), as \( n \to \infty \),

\[
\mathbb{E} [ M^r(n); \tau_x > n, M(n) > n^{1/2+\varepsilon/2} ] = o \left( \mathbb{E}[\tau_x \wedge n] \vee 1 \right).
\]

**Proof.** For every fixed \( a > 0 \) one has

\[
P \left( M(n) > r, \tau_x > n \right)
\leq P \left( M(n) > r, \max_{j \leq n} |X(j)| \leq ar \right) + P \left( \max_{j \leq n} |X(j)| > ar, \tau_x > n \right). \tag{2.10}
\]

Using first the standard union bound and then the Fuk-Nagaev-type inequality from Corollary 23 in [9], one gets

\[
P \left( M(n) > r, \max_{j \leq n} |X(j)| \leq ar \right) \leq 2dn \left( \frac{\sqrt{d}e}{a} \right)^{1/a} \left( \frac{n}{\tau^2} \right)^{1/(a\sqrt{a})}. \tag{2.11}
\]

Furthermore,

\[
P \left( \max_{j \leq n} |X(j)| > ar, \tau_x > n \right) \leq \sum_{j=1}^n P \left( |X(j)| > ar, \tau_x > n \right)
\leq \sum_{j=1}^n P \left( |X(j)| > ar, \tau_x > j-1 \right)
= \mathbb{E}[\tau_x \wedge n] P(|X| > ar). \tag{2.12}
\]

Combining (2.10)–(2.12), we conclude that

\[
P \left( M(n) > r, \tau_x > n \right) \leq 2dn \left( \frac{\sqrt{d}e}{a} \right)^{1/a} \left( \frac{n}{\tau^2} \right)^{1/(a\sqrt{a})} + \mathbb{E}[\tau_x \wedge n] P(|X| > ar).
\]

Choosing here \( a = \frac{2\varepsilon}{3d((1+\varepsilon)r+5)} \) and integrating the latter bound, one easily gets the bound

\[
\mathbb{E} \left[ (M(n))^r; \tau_x > n, M(n) > n^{1/2+\varepsilon/2} \right]
\leq C(a) \left( n^{-3/2} + \mathbb{E}[\tau_x \wedge n] \mathbb{E} \left[ X^r; |X| > an^{1/2+\varepsilon/2} \right] \right). \tag{2.13}
\]

Thus, the proof is complete. \( \Box \)
Finally, we will require the following results from [16].

**Lemma 2.6.** For every $\beta < p$ we have

$$E[x^{\beta/2}] \leq C(1 + |x|^\beta)$$  \hspace{1cm} (2.14)

and

$$E[M^\beta(\tau_x)] \leq C(1 + |x|^\beta),$$  \hspace{1cm} (2.15)

where $M(\tau_x) := \max_{x \leq \tau_x} |x + S(x)|$.

This is the statement of Theorem 3.1 of [16]. One has only to notice that $e(\Gamma, R)$ in that theorem is denoted by $p$ in our paper.

### 3 First proof of Theorem 1.1

Since $K$ is starlike there exists $x_0 \in K$ with $|x_0| = 1$, $x_0 + K \subset K$ and $R_0$ such that $\text{dist}(R_0x_0 + K, \partial K) > 1$. For $k \geq 0$ set

$$g_k = k^{1/2-\gamma}R_0x_0,$$

where $\gamma \in (0, \min(1/2, p))$. First we will show that it is sufficient to show convergence of

$$E[u(x + g_k + S(k)); \tau_x > k]$$

as $k$ to infinity.

**Lemma 3.1.** For any $x \in K$, as $k \to \infty$,

$$E[u(x + g_k + S(k)); \tau_x > k] - E[u(x + S(k)); \tau_x > k] \to 0.$$  \hspace{1cm} (3.1)

**Proof.** Consider first the case $p \geq 1$. Using (2.4), we obtain

$$|E[u(x + g_k + S(k)); \tau_x > k] - E[u(x + S(k)); \tau_x > k]|$$

$$= |E[u(x + g_k + (S(k) - u(x + S(k))); \tau_x > k]|$$

$$\leq C|g_k|E[|x + S(k)|^{p-1}; \tau_x > k] + C|g_k|^pE(\tau_x > k)$$

$$\leq C|g_k|E[|x(S(k))|^{p-1}; \tau_x > k] + C(1 + |x|^{p-1}|g_k|^pE(\tau_x > k).$$  \hspace{1cm} (3.2)

Using the Markov inequality and (2.14) with $\beta = p - p\gamma$, we get

$$|g_k|^pE(\tau_x > k) \leq Ck^{p/2-p\gamma}E|\tau_x^{p/2-p\gamma/2}| \to 0, \quad k \to \infty.$$  \hspace{1cm} (3.3)

Furthermore,

$$E[|S(k)|^{p-1}; \tau_x > k]$$

$$\leq k^{(1+\epsilon)(p-1)/2}P(\tau_x > k) + E[|S(k)|^{p-1}; \tau_x > k, |S(k)| > k^{(1+\epsilon)/2}]$$

$$\leq k^{(1+\epsilon)(p-1)/2}P(\tau_x > k) + k^{-(1+\epsilon)/2}E[|S(k)|^{p}; \tau_x > k, |S(k)| > k^{(1+\epsilon)/2}].$$  \hspace{1cm} (3.4)

Choosing $\epsilon < \gamma/(p-1)$, applying the Markov inequality and using (2.14) with $\beta = p - \epsilon(p-1)$, we conclude that

$$|g_k|^k^{(1+\epsilon)(p-1)/2}P(\tau_x > k) \leq |g_k|^k^{(1+\epsilon)(p-1)/2}\frac{E|\tau_x^{p/2-\epsilon(p-1)/2}|}{k^{p/2-\epsilon(p-1)/2}} \to 0.$$  \hspace{1cm} (3.5)

If $p > 2$ then $E\tau_x$ is finite and, by Lemma 2.5,

$$|g_k|^{-(1+\epsilon)/2}E[|S(k)|^{p}; \tau_x > k, |S(k)| > k^{(1+\epsilon)/2}] \to 0.$$  \hspace{1cm} (3.6)
If \( p \leq 2 \) then, using (2.14) once again, we have
\[
E[|x_\tau| k] \leq k^{1-p/2+\delta/2}E[|x|^{p/2-\delta/2}] \leq C(1 + |x|^p)k^{1-p/2+\delta/2}.
\]

Combining this estimate with Lemma 2.5, we obtain
\[
E \left[ |S(k)|^p ; |S_x| > k, |S(k)| > k^{(1+\varepsilon)/2} \right] \\
\leq k^{-(2-\delta - p)(1+\varepsilon)/2}E \left[ |S(k)|^{2+\delta}; |S_x| > k, |S(k)| > k^{(1+\varepsilon)/2} \right] \rightarrow 0.
\]

Therefore, (3.6) remains valid for \( p \leq 2 \). Combining (3.5) and (3.6), we conclude that
\[
|g_k|E[|S(k)|^{p-1}; |S_x| > k] \rightarrow 0.
\]

Applying this and (3.3) to the right hand side in (3.2), we have (3.1).

We are left to consider the case \( p < 1 \). By (2.6), we immediately arrive at
\[
|E[u(x + g_k + S(k)) - u(x + S(k)); |S_x| > k]| \leq C|g_k|^pE(\tau_x > k)
\]
\[
\leq C|g_k|^p\frac{E[|x|^{p/2-\delta/2}]}{k^{p/2-\delta/2}} \rightarrow 0.
\]

Now we prove the existence of the limit of the sequence \( E[u(x + g_k + S(k)); |S_x| > k] \).

**Proposition 3.2.** There exist a finite function \( V(x) \) such that
\[
\lim_{k \to \infty} E[u(x + g_k + S(k)); |S_x| > k] = V(x).
\]

We shall split the proof of this proposition into several steps. To this end we shall use the following decomposition:
\[
u(x + g_k + S(k))\mathbb{I}\{\tau_x > k\}
\]
\[
= u(x) + \sum_{l=1}^{k} \left[ u(x + g_l + S(l))\mathbb{I}\{\tau_x > l\} - u(x + g_{l-1} + S(l-1))\mathbb{I}\{\tau_x > l - 1\} \right]
\]
\[
= u(x) - \sum_{l=1}^{k} \left[ u(x + g_l + S(l))\mathbb{I}\{\tau_x = l\} \right]
\]
\[
+ \sum_{l=1}^{k} \left[ u(x + g_l + S(l)) - u(x + g_{l-1} + S(l-1))\right]\mathbb{I}\{\tau_x > l - 1\}
\]
\[
= u(x) - u(x + g_{\tau_x} + S(\tau_x))\mathbb{I}\{\tau_x \leq k\}
\]
\[
+ \sum_{l=1}^{k} \left[ u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))\right]\mathbb{I}\{\tau_x > l - 1\}
\]
\[
+ \sum_{l=1}^{k} \left[ u(x + g_{l-1} + S(l)) - u(x + g_{l-1} + S(l-1))\right]\mathbb{I}\{\tau_x > l - 1\}
\]
\[
=: u(x) - W_k^{(1)}(x) + W_k^{(2)}(x) + W_k^{(3)}(x). \tag{3.7}
\]

The proposition will follow if we show that the expectations of all three random variables in (3.7) converge, as \( k \to \infty \), to finite limits.

**Lemma 3.3.** The sequence \( W_k^{(1)}(x) \) converges almost surely and in \( L^1 \) towards \( u(x + g_{\tau_x} + S(\tau_x)) \). Furthermore,
\[
E[u(x + g_{\tau_x} + S(\tau_x)) \leq C(1 + |x|^{p-\gamma})]. \tag{3.8}
\]
Alternative constructions of a harmonic function in a cone

\textbf{Proof.} The almost sure convergence is immediate from the fact that the sequence $W^{(1)}_k$ is increasing. Thus, it remains to show that (3.8) holds.

Since $x + S(\tau_x) \notin K$, $\text{dist}(x + g_{\tau_x} + S(\tau_x), \partial K) \leq |g_{\tau_x}|$ in the case when $x + g_{\tau_x} + S(\tau_x) \in K$.

Assume first that $p < 1$. Combining (2.6) and (2.14), we obtain

$$E[u(x + g_{\tau_x} + S(\tau_x))] \leq CE[|g_{\tau_x}|^p] \leq CE[t_{\tau_x}^{p/2 - p\gamma}] \leq C(1 + |x|^{p-\gamma}).$$

Consider now the case $p \geq 1$. Then, using the upper bound (2.2), we obtain

$$E[u(x + g_{\tau_x} + S(\tau_x))] \leq CE[|g_{\tau_x}|(|x| + |g_{\tau_x}| + |S(\tau_x)|)^{p-1}] \leq C \left( |x|^{p-1}E[|g_{\tau_x}|] + E[|g_{\tau_x}|^p + E[|g_{\tau_x}|M(\tau_x)^{p-1}] \right).$$

Recalling the definition of the sequence $g_k$, we have

$$E[u(x + g_{\tau_x} + S(\tau_x))] \leq C|x|^{p-1}E[t_{\tau_x}^{1/2 - p\gamma} + C|\tau_x|^{p/2 - p\gamma} + CE \left[ t_{\tau_x}^{1/2 - \gamma} M(\tau_x)^{p-1} \right].$$

Using (2.14), we conclude that the first two summands are bounded from above by $C(1 + |x|^{p-2\gamma})$. Applying the Hölder inequality with some $p' \in (p, p + \gamma)$ to the third summand, we get

$$E \left[ t_{\tau_x}^{1/2 - \gamma} M(\tau_x)^{p-1} \right] \leq \left( E \left[ t_{\tau_x}^{p'/2 - p\gamma} \right] \right)^{1/p'} \left( E \left[ M^{(p-1)p'/p\gamma}(\tau_x) \right] \right)^{(p'-1)/p'}$$

By (2.15), $E M^\beta(\tau_x) \leq C_\beta (1 + |x|^\beta)$, $\beta < p$. From this inequality and from (2.14), we infer that

$$E \left[ t_{\tau_x}^{1/2 - \gamma} M(\tau_x)^{p-1} \right] \leq C(1 + |x|^{1-\gamma})(1 + |x|^{p-1}).$$

As a result, (3.8) holds also for $p \geq 1$. \hfill \qed

\textbf{Lemma 3.4.} There exists $W^{(2)}(x)$ such that $W^{(2)}_k(x)$ converges a.s. and in $L^1$ towards $W^{(2)}(x)$. Moreover,

$$E[W^{(2)}(x)] \leq C(1 + |x|^{p-\gamma}).$$

\textbf{Proof.} It is clear that all claims in the lemma will follow from

$$\sum_{l=1}^{\infty} E[|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l)); \tau_x > l - 1|] \leq C(1 + |x|^{p-\gamma}).$$

First we will consider the case $p \geq 1$. Note that if $x + g_{l-1} + S(l) \in K$ then, by (2.4),

$$|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))| \leq C|g_l - g_{l-1}|^p + C|g_l - g_{l-1}| |x + g_{l-1} + S(l)|^{p-1}$$

and, similarly, if $x + g_l + S(l) \in K$ then

$$|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))| \leq C|g_l - g_{l-1}|^p + C|g_l - g_{l-1}| |x + g_l + S(l)|^{p-1}.$$ 

Hence, if either $x + g_l + S(l) \in K$ or $x + g_{l-1} + S(l) \in K$ then

$$|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))| \leq C|g_l - g_{l-1}|^p + C|g_l - g_{l-1}| |x + g_{l-1}|^{p-1} + |S(l - 1)|^{p-1} + |X(l)|^{p-1}. \quad (3.11)$$
Since \( u = 0 \) outside of the cone the inequality (3.11) is obvious if both \( x + g_l + S(l) \notin K \) and \( x + g_{l-1} + S(l-1) \notin K \). Using (3.11), we have

\[
\sum_{l=1}^{k} |E[u(x + g_l + S(l)) - u(x + g_{l-1} + S(l)); \tau_x > l - 1]|
\]

\[
\leq C \sum_{l=1}^{k} P(\tau_x > l - 1) \left( |g_l - g_{l-1}|^p + |g_l - g_{l-1}| |g_l|^{p-1} \right)
\]

\[
+ C \sum_{l=1}^{k} |g_l - g_{l-1}|E[|x|^{p-1} + |S(l-1)|^{p-1} + |X(l)|^{p-1}; \tau_x > l - 1]. \tag{3.12}
\]

By (2.14), noting that \( |g_l - g_{l-1}| \leq C l^{-1/2-\gamma} \) we obtain for every \( p \geq 1 \),

\[
\sum_{l=1}^{k} P(\tau_x > l - 1) \left( |g_l - g_{l-1}|^p + |g_l - g_{l-1}| |g_l|^{p-1} \right)
\]

\[
\leq C \sum_{l=1}^{k} p^{p/2-1-p\gamma} P(\tau_x > l - 1)
\]

\[
\leq C E[\tau_x^{p/2-p\gamma}]. \tag{3.13}
\]

Similarly,

\[
(|x|^{p-1} + E[|X(l)|^{p-1}] \sum_{l=1}^{k} |g_l - g_{l-1}| P(\tau_x > l)
\]

\[
\leq C(1 + |x|^{p-1}) \sum_{l=1}^{k} P(\tau_x > l) l^{-1/2-\gamma}
\]

\[
\leq C(1 + |x|^{p-1}) E[\tau_x^{1/2-\gamma}] \leq C(1 + |x|^{p-\gamma}). \tag{3.14}
\]

It follows from (3.4) and from Lemma 2.5 that

\[
E \left[ |S(l-1)|^{p-1}; \tau_x > l - 1 \right] \leq l^{(p-1)/2+\varepsilon(p-1)/2} P(\tau_x > l - 1) + C E[\tau_x] l^{-1/2-\varepsilon/2}
\]

in the case \( p > 2 \). Therefore, for \( \varepsilon < \gamma/(p-1) \),

\[
\sum_{l=1}^{k} |g_l - g_{l-1}| E \left[ |S(l-1)|^{p-1}; \tau_x > l - 1 \right]
\]

\[
\leq C \sum_{l=1}^{k} p^{p/2-1-\gamma/2} P(\tau_x > l - 1) + C E[\tau_x] \sum_{l=1}^{k} l^{-1-\gamma}
\]

\[
\leq C E[\tau_x^{p/2-\gamma/2}] + C E[\tau_x].
\]

Then, taking into account (2.14),

\[
\sum_{l=1}^{k} |g_l - g_{l-1}| E \left[ |S(l-1)|^{p-1}; \tau_x > l - 1 \right] \leq C(1 + |x|^{p-\gamma}). \tag{3.15}
\]

Similarly one shows that this relation is true in the case \( p \leq 2 \). (Here one has to use the assumption \( E|X|^{2+\delta} < \infty \) instead of \( E|X|^p < \infty \).) Plugging (3.13)–(3.15) into (3.12), we infer that (3.10) holds in the case \( p \geq 1 \).
Alternative constructions of a harmonic function in a cone

Assume now that $p < 1$. On the event $\{\tau_x > l - 1\}$ one has

$$\text{dist}(x + g_{l-1} + S(l-1), \partial K) \geq (l - 1)^{1/2-\gamma}.$$ 

This implies that

$$x + g_{l-1} + S(l) \in K \quad |x + g_{l-1} + S(l)| \geq \frac{(l - 1)^{1/2-\gamma}}{2}$$

provided that $\tau_x > l - 1$ and $|X(l)| \leq \frac{(l-1)^{1/2-\gamma}}{2}$. From these observations and from (2.5) we obtain

$$E[|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))|; \tau_x > l - 1, |X(l)| \leq (l - 1)^{1/2-\gamma}/2] \leq C|g_l - g_{l-1}|(l-1)^{(p-1)(1/2-\gamma)}P(\tau_x > l - 1).$$

Furthermore, by (2.6),

$$E[|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))|; \tau_x > l - 1, |X(l)| > (l - 1)^{1/2-\gamma}/2] \leq C|g_l - g_{l-1}|P(\tau_x > l - 1)P(|X(l)| > (l - 1)^{1/2-\gamma}/2).$$

Recalling that $E|X(1)|^{2+\delta} < \infty$ and that $|g_l - g_{l-1}| \leq C(l - 1)^{-1/2-\gamma}$ for $l > 2$, one gets easily

$$E[|u(x + g_l + S(l)) - u(x + g_{l-1} + S(l))|; \tau_x > l - 1] \leq C(l - 1)^{p/2-1-\gamma}P(\tau_x > l - 1), \quad l \geq 2.$$ 

Summing over $l$ and using (2.14) we complete the proof.

**Lemma 3.5.** For every $x \in K$,

$$E \left[ \sum_{l=0}^{\infty} |f(x + g_l + S(l))I[\tau > l] \right] \leq C \left( 1 + |x|^{p-\gamma} + \frac{|x|^p}{(\text{dist}(x, \partial K))^{\gamma}} \right)$$

(3.16)

and

$$E[W_k^{(3)}(x)] \rightarrow E \left[ \sum_{l=0}^{\infty} f(x + g_l + S(l))I[\tau > l] \right].$$

(3.17)

**Proof.** Recalling the definition of the function $f$, we have

$$E[W_k^{(3)}(x)] = E \left[ \sum_{l=0}^{k-1} f(x + g_l + S(l))I[\tau > l] \right].$$

This equality yields that (3.17) is a simple consequence of (3.16).

Applying Lemma 2.4 and using the elementary bound $\text{dist}(y + g_l, \partial K) \geq l^{1/2-\gamma}$ for
Alternative constructions of a harmonic function in a cone

$y \in K$, following from the choice of $x_0$ and $R_0$ in the definition of $g_l$, we have

$$
\sum_{l=0}^{k-1} \mathbb{E}[|f(x + g_{l-1} + S(l-1))|; \tau_x > l-1] \\
\quad \leq C \frac{|x|^p}{(\text{dist}(x, \partial K))^{2+\delta}} + C \sum_{l=1}^{k-1} \mathbb{E} \left[ \frac{|x + g_l + S(l)|^p}{(\text{dist}(x + g_l + S(l), \partial K))^{2+\delta}; \tau_x > l} \right] \\
\quad \leq C|x|^p \sum_{l=0}^{k-1} \mathbb{E} \left[ (\text{dist}(x + g_l + S(l), \partial K))^{-2-\delta}; \tau_x > l \right] \\
\quad \quad + C \sum_{l=1}^{k-1} |g_l|^{p-2-\delta} \mathbb{P}(\tau_x > l) \\
\quad \quad + C \sum_{l=1}^{k-1} |g_l|^{-2-\delta} \mathbb{E}[|S(l)|^p; \tau_x > l].
$$

Choosing $\gamma$ sufficiently small, we have

$$
\sum_{l=1}^{k-1} |g_l|^{p-2-\delta} \mathbb{P}(\tau_x > l) \leq C \sum_{l=1}^{k-1} |l|^{p-2-1-\gamma} \mathbb{P}(\tau_x > l) \\
\quad \leq C \mathbb{E}[\tau_x^{p-2-\gamma/2}] \leq C(1 + |x|^{p-\gamma}). \tag{3.18}
$$

We next show that

$$
\sum_{l=1}^{k-1} |g_l|^{-2-\delta} \mathbb{E}[|S(l)|^p; \tau_x > l] \leq C(1 + |x|^{p-\gamma}). \tag{3.19}
$$

Assume first that $p > 2$. Applying Lemma 2.5, we have

$$
\mathbb{E}[|S(l)|^p; \tau_x > l] \leq l^{p(1+\varepsilon)/2} \mathbb{P}(\tau_x > l) + C \mathbb{E}[\tau_x].
$$

Combining this with the estimate $|g_l| \geq c l^{1/2-\gamma}$, we obtain, for $\gamma < \frac{\delta}{5+2\delta}$ and $\varepsilon < \frac{5\gamma - 2\gamma\delta}{p}$,

$$
\sum_{l=1}^{k-1} |g_l|^{-2-\delta} \mathbb{E}[|S(l)|^p; \tau_x > l] \\
\quad \leq C \sum_{l=1}^{k-1} l^{p(1+\varepsilon)/2-(2+\delta)(1/2-\gamma)} \mathbb{P}(\tau_x > l) + C \mathbb{E}[\tau_x] \sum_{l=1}^{k-1} l^{-(2+\delta)(1/2-\gamma)} \\
\quad \leq C \sum_{l=1}^{k-1} l^{p/2-\gamma/2-1} \mathbb{P}(\tau_x > l) + C \mathbb{E}[\tau_x] \\
\quad \leq C \mathbb{E}[\tau_x^{p/2-\gamma/2}].
$$

Taking into account Lemma 2.6, we get (3.19) for $p > 2$.

If $p \leq 2$ then the moment of order $2 + \delta$ is finite and, consequently,

$$
\mathbb{E}[|S(l)|^p; \tau_x > l] \\
\quad \leq l^{p(1+\varepsilon)/2} \mathbb{P}(\tau_x > l) + l^{-(2+\delta-p)(1+\varepsilon/2)} \mathbb{E}[|S(l)|^{2+\delta}; |S(l)| > l^{(1+\varepsilon)/2}, \tau_x > l] \\
\quad \leq l^{p(1+\varepsilon)/2} \mathbb{P}(\tau_x > l) + C l^{-(2+\delta-p)(1+\varepsilon/2)} \mathbb{E}[\tau_x \wedge l],
$$

where in the last step we used Lemma 2.5 once again. Noting that

$$
\mathbb{E}[\tau_x \wedge l] \leq l^{1-p/2+\gamma/2} \mathbb{E}[\tau_x^{p/2-\gamma/2}]
$$
we obtain
\[
E[|S(l)|^p; \tau_x > l] \leq p^{(1+\varepsilon)/2} \mathbb{P}(\tau_x > l) + C l^{-(2+\delta-p)(1+\varepsilon/2)+1-p/2+\gamma/2} E[\gamma^{p/2-\gamma}/2].
\]

Summing over \( l \) we infer that (3.19) holds also for \( p \leq 2 \), provided that \( \gamma \) and \( \varepsilon \) are sufficiently small.

Using the bound \( \text{dist}(y + g_l, \partial K) \geq l^{1/2-\gamma} \) and choosing \( \gamma \) sufficiently small, we conclude that
\[
\sum_{l=g(x)}^{\infty} E \left[ (\text{dist}(x + g_l + S(l)), \partial K)^{-2-\delta}; \tau_x > l \right]
\leq \sum_{l=g(x)}^{\infty} l^{-(1/2-\gamma)(2+\delta)} \leq C g^{-\gamma}(x).
\]

Furthermore, if \( |S(l)| \leq g(x)/2 \) then \( \text{dist}(x + g_l + S(l)), \partial K) > g(x)/2 \). Thus, by the Chebyshev inequality,
\[
E \left[ (\text{dist}(x + g_l + S(l)), \partial K)^{-2-\delta}; \tau_x > l \right] \leq C g(x)^{-2-\delta} + C l^{-(1/2-\gamma)(2+\delta)} \frac{l}{g^2(x)}.
\]

Consequently,
\[
\sum_{l=0}^{g(x)} E \left[ (\text{dist}(x + g_l + S(l)), \partial K)^{-2-\delta}; \tau_x > l \right] \leq C g^{-\gamma}(x).
\]

As a result,
\[
\sum_{l=0}^{\infty} E \left[ (\text{dist}(x + g_l + S(l)), \partial K)^{-2-\delta}; \tau_x > l \right] \leq C g^{-\gamma}(x).
\]

Combining this with (3.18) and (3.19), we arrive at (3.16). \( \Box \)

The claim of Proposition 3.2 is immediate from Lemmas 3.3, 3.4 and 3.5. Furthermore, we have, for a sufficiently small \( \gamma \), the estimate
\[
|V(x) - u(x)| \leq C \left( 1 + |x|^{p-\gamma} + \frac{|x|^p}{\text{dist}(x, \partial K)^\gamma} \right).
\]  

(3.20)

**Lemma 3.6.** The function \( V \) possesses the following properties.

(a) For any \( \gamma > 0, R > 0 \), uniformly in \( x \in D_{R,\gamma} \) we have \( V(tx) \sim u(tx) \) as \( t \to \infty \).

(b) For all \( x \in K \) we have \( V(x) \leq C(1 + |x|^p) \).

(c) The function \( V \) is harmonic for the killed random walk, that is
\[
V(x) = E[V(x + S(n_0)), \tau_x > n_0], \quad x \in K, n_0 \geq 1.
\]

(d) The function \( V \) is strictly positive on \( K_+ \).

(e) If \( x \in K \), then \( V(x) \leq V(x + x_0) \), for all \( x_0 \) such that \( x_0 + K \subset K \).

The proof is identical with that of Lemma 13 in [9], for the proof of (c) one has to notice that (3.20) implies that \( V(x) = u(x) + O(|x|^{p-\gamma}) \) for \( x \in D_{R,\gamma} \).
4 Proof of Corollary 1.2

As we have mentioned in the introduction, the proofs of the claims in the corollaries are quite close to that in [9]. We demonstrate the needed changes by deriving the tail asymptotics for $\tau_x$. Proofs of other results can similarly be adapted to the present setting.

Let

$$K_{n,\epsilon} := \left\{ x \in K : \text{dist}(x, \partial K) \geq n^{1/2-\epsilon} \right\},$$

where $\epsilon < \gamma/(1 + p)$. Similarly to the proof of Lemma 20 in [9] one can show that

$$u(y + g_k) = (1 + o(1))u(y), \quad y \in K_{n,\epsilon}, |y| \leq \sqrt{n}$$

(4.1)

uniformly in $k \leq n^{1-\epsilon}$. Indeed, by (2.5),

$$|u(y + g_k) - u(y)| \leq C|g_k||y|^{p-1} = C\frac{|g_k|}{|y|}|y|^{p} \leq Cn^{\epsilon-\gamma}n^{p/2}.$$  

Also, by the lower bound in (2.2)

$$|u(y)| \geq Cn^{p/2-\epsilon}.$$  

Hence,

$$\frac{|u(y + g_k) - u(y)|}{|u(y)|} \leq Cn^{(1+p)\epsilon-\gamma},$$  

which proves (4.1), as $(1 + p)\epsilon < \gamma$.

Then, it follows from (4.1) that for any sequence $\theta_n \to 0$,

$$E [u(x + S(\nu_n)); \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}, |x + S(\nu_n)| \leq \theta_n \sqrt{n}]$$

$$\sim E [u(x + g_{\nu_n} + S(\nu_n)); \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}, |x + S(\nu_n)| \leq \theta_n \sqrt{n}],$$

where

$$\nu_n := \inf \{ n \geq 0 : x + S(n) \in K_{n,\epsilon} \}.$$  

Applying this to (50) in [9], we obtain

$$P(\tau_x > n, \nu_n \leq n^{1-\epsilon})$$

$$= \frac{x + o(1)}{n^{p/2}} E [u(x + g_{\nu_n} + S(\nu_n)); \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}]$$

$$+ \frac{1}{n^{p/2}} E \left[ |x + S(\nu_n)|^p; \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}, |x + S(\nu_n)| > \theta_n \sqrt{n} \right].$$

In view of Lemma 24 in [9], O-term is $o(n^{-p/2})$. Therefore, the proof will be completed if we show that

$$E [u(x + g_{\nu_n} + S(\nu_n)); \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}] \to V(x).$$  

(4.2)

According to (3.7),

$$E [u(x + g_{\nu_n} + S(\nu_n)); \tau_x > \nu_n, \nu_n \leq n^{1-\epsilon}]$$

$$= E[u(x) - W_{\nu_n}^{(1)}(x) + W_{\nu_n}^{(2)}(x) + W_{\nu_n}^{(3)}(x); \nu_n \leq n^{1-\epsilon}].$$

Now note that $P(\nu_n \leq n^{1-\epsilon}) \to 1$ by the functional central limit theorem. Therefore, since $\nu_n \to \infty$, as $n \to \infty$, by Lemmas 3.3 and 3.4 and the dominated convergence theorem we obtain, as $n \to \infty$,

$$E[u(x) - W_{\nu_n}^{(1)}(x) + W_{\nu_n}^{(2)}(x); \nu_n \leq n^{1-\epsilon}]$$

$$\to u(x) - E[u(x + g_{\tau_x} + S(\tau_x)) + E|W^{(2)}(\nu_n)|].$$
Assume first that

\[ P \]

The first summand on the right hand side converges to zero due to the fact that

Thus, (4.2) will follow from the convergence

\[ E \left[ \sum_{l=0}^{\infty} f(x + g_l + S(l)) I\{\tau > l\} \right]. \] \hfill (4.3)

It is immediate from the definition of \( f(x) \) that the sequence

\[ Y_k := W_k^{(3)}(x) - \sum_{l=0}^{k-1} f(x + g_l + S(l)) I\{\tau_x > l\} \]

is a martingale. Upper bound (3.16) together with the dominated convergence theorem imply that

\[ E \left[ \sum_{l=0}^{\tau_x-1} f(x + g_l + S(l)) I\{\tau_x > l\}; \nu_n \leq n^{1-\epsilon} \right] \to E \left[ \sum_{l=0}^{\infty} f(x + g_l + S(l)) I\{\tau_x > l\} \right]. \] \hfill (4.4)

Furthermore, by the optional stopping theorem,

\[ E[Y_{\nu_n}; \nu_n \leq n^{1-\epsilon}] = E[Y_{\nu_n \wedge n^{1-\epsilon}}; \nu_n \leq n^{1-\epsilon}] = E[Y_{\nu_n \wedge n^{1-\epsilon}}; \nu_n > n^{1-\epsilon}] \]

\[ = -E[Y_{\nu_n \wedge n^{1-\epsilon}}; \nu_n > n^{1-\epsilon}] \]

\[ = -E[W_{n^{1-\epsilon}}^{(3)}(x); \nu_n > n^{1-\epsilon}] + E \left[ \sum_{l=0}^{n^{1-\epsilon}-1} f(x + g_l + S(l)) I\{\tau_x > l\}; \nu_n > n^{1-\epsilon} \right]. \]

Using (3.16), the dominated convergence theorem and the fact that \( P(\nu_n > n^{1-\epsilon}) \) converges to zero once again, we infer that

\[ E[Y_{\nu_n}; \nu_n \leq n^{1-\epsilon}] = -E[W_{n^{1-\epsilon}}^{(3)}(x); \nu_n > n^{1-\epsilon}] + o(1). \]

Assume first that \( p < 1 \). Recalling the definition of \( W_{n^{1-\epsilon}}^{(3)} \) and using (2.6), we have

\[ |W_{n^{1-\epsilon}}^{(3)}| \leq C \sum_{l=1}^{k} |X(l)|^p I\{\tau_x > l - 1\}. \]

Then, for every fixed \( N \geq 1 \),

\[ E[|W_{n^{1-\epsilon}}^{(3)}(x); \nu_n > n^{1-\epsilon}|] \]

\[ \leq C E \left[ \sum_{l=1}^{N} |X(l)|^p; \nu_n > n^{1-\epsilon} \right] + C \sum_{l=N+1}^{n^{1-\epsilon}} E[|X(1)|^p P(\tau_x > l - 1, \nu_n > l - 1)]. \]

The first summand on the right hand side converges to zero due to the fact that \( P(\nu_n > n^{1-\epsilon}) \to 0 \). Furthermore, by Lemma 14 in [9],

\[ P(\nu_n > n^{1-\epsilon}, \tau_x > n^{1-\epsilon}) \leq \exp\{-Cn^{\epsilon}\}. \] \hfill (4.5)

Therefore, we obtain

\[ \sum_{l=N+1}^{n^{1-\epsilon}} P(\tau_x > l - 1, \nu_n > l - 1) \leq \sum_{l=N+1}^{n^{1-\epsilon}} P(\tau_x > l - 1, \nu_n > l - 1) \]

\[ \leq \sum_{l=N+1}^{\infty} e^{-Cn^{\epsilon}}. \]
Alternative constructions of a harmonic function in a cone

Letting here $N \to \infty$, we conclude that

$$E[|W^{(3)}_{n^{1-\epsilon}}(x)|; \nu_n > n^{1-\epsilon}] \to 0.$$  

It remains to prove this relation for $p \geq 1$. In this case, using (2.4), we have

$$|W^{(3)}_k| \leq C \sum_{l=1}^{k} (|X(l)|^p + |X(l)| x + g_{l-1} + S(l-1)|^{p-1}) I[\tau_x > l-1].$$

The summands with $|X(l)|^p$ have been already considered. For the remaining summands we have for $N \geq 1$,

$$E \left[ \sum_{l=1}^{n^{1-\epsilon}} |X(l)| x + g_{l-1} + S(l-1)|^{p-1} I[\tau_x > l-1]; \nu_n > n^{1-\epsilon} \right]$$

$$\leq E \left[ \sum_{l=N+1}^{n^{1-\epsilon}} |X(l)| x + g_{l-1} + S(l-1)|^{p-1}; \nu_n > n^{1-\epsilon} \right]$$

$$+ E[|X(1)|] \sum_{l=N+1}^{n^{1-\epsilon}} E[|x + g_{l-1} + S(l-1)|^{p-1}; \tau_x > l-1, \nu_n > l-1].$$

The first summand converges again to zero since $P(\nu_n > n^{1-\epsilon}) \to 0$. For the second summand applying the Cauchy-Schwarz inequality and then using (4.5), we have

$$\mathbf{E} \left[ |x + g_{l-1} + S(l-1)|^{p-1}; \tau_x > l-1, \nu_n > l-1 \right]$$

$$\leq (\mathbf{E} |x + g_{l-1} + S(l-1)|^p)^{(p-1)/p} \mathbf{P}^{1/p}(\tau_x > l-1, \nu_n > l-1)$$

$$\leq C n^{p/2} \epsilon^{-(p-1)/2} e^{-CT}.$$

Therefore, letting $N \to \infty$, we complete the proof.

5 Second proof of Theorem 1.1

For every $\epsilon > 0$ define

$$\tilde{K}_{n, \epsilon} := \left\{ x \in K : \text{dist}(x, \partial K) \geq \frac{1}{2} \left( n^{1/2-\epsilon} + \frac{|x|}{n^{\epsilon/2}} \right) \right\}.$$  

5.1 Preliminary estimates

The next statement is the most important step in this proof of Theorem 1.1.

**Proposition 5.1.** Assume that the conditions of Theorem 1.1 are valid. Then, for every sufficiently small $\epsilon > 0$ there exists $q > 0$ such that

$$\max_{k \leq n} \mathbf{E}[u(x + S(k)); \tau_x > k] - u(x) \leq \frac{C}{n^q} u(x), \quad x \in \tilde{K}_{n, \epsilon}.$$

**Lemma 5.2.** For sufficiently small $\epsilon$ there exists $q > 0$ such that

$$\max_{k \in [\sqrt{n}, n]} |\mathbf{E}[u(x + S(k)); \tau_x > k] - u(x)| \leq \frac{C}{n^q}, \quad x \in \tilde{K}_{n, \epsilon}.$$  

**Proof.** For every $x \in K$ define

$$x_k^+ = x + g_k = x + k^{1/2-\gamma} R_0 x_0.$$  

EJP 24 (2019), paper 92.
Clearly,
\[
\begin{align*}
E[u(x + S(k)); \tau_x > k] &= E[u(x + S(k)) - u(x_k^+ + S(k)); \tau_x > k] + E[u(x_k^+ + S(k)); \tau_x > k].
\end{align*}
\]

If \( p \geq 1 \) then, using (2.4), we get
\[
\begin{align*}
E[[u(x + S(k)) - u(x_k^+ + S(k)); \tau_x > k] &\leq Ck^{1/2-\gamma}E \left[ |x|^{p-1} + |S(k)|^{p-1} + k^{(1/2-\gamma)(p-1)} \right] \\
&\leq Ck^{1/2-\gamma} \left( |x|^{p-1} + k^{(p-1)/2} \right).
\end{align*}
\]

In the case \( p < 1 \) we use (2.6) to obtain
\[
\begin{align*}
E[[u(x + S(k)) - u(x_k^+ + S(k)); \tau_x > k] &\leq C|g_k|^p \leq Ck^{p(1/2-\gamma)}.
\end{align*}
\]

Combining these two cases, we have
\[
\begin{align*}
E[[u(x + S(k)) - u(x_k^+ + S(k)); \tau_x > k] &\leq Ck^{1/2-\gamma} \left( |x|^{p-1}1 \{p \geq 1\} + k^{(p-1)/2} \right). \\
\end{align*}
\]

Next,
\[
\begin{align*}
E[u(x_k^+ + S(k)); \tau_x > k] &= u(x_k^+) + \sum_{l=1}^{k} (E[u(x_k^+ + S(l)); \tau_x > l] - E[u(x_k^+ + S(l - 1)); \tau_x > l - 1]) \\
&= u(x_k^+) + \sum_{l=1}^{k} E[u(x_k^+ + S(l)) - u(x_k^+ + S(l - 1); \tau_x > l - 1] \\
&\quad - \sum_{l=1}^{k} E[u(x_k^+ + S(l)); \tau_x = l] \\
&= u(x_k^+) + \sum_{l=1}^{k} E[f(x_k^+ + S(l - 1)); \tau_x > l - 1] - E[u(x_k^+ + S(\tau_x)); \tau_x \leq k].
\end{align*}
\]

Using (2.4) and (2.6) once again, we have
\[
|u(x_k^+) - u(x)| \leq Ck^{1/2-\gamma} \left( |x|^{p-1}1 \{p \geq 1\} + k^{(1/2-\gamma)(p-1)} \right). 
\]

By Lemma 2.4,
\[
\left| \sum_{l=1}^{k} E[f(x_k^+ + S(l - 1)); \tau_x > l - 1] \right| \leq C \sum_{l=0}^{k-1} E \left[ \frac{|x_k^+ + S(l)|^p}{\text{dist}(x_k^+ + S(l), \partial K)^{2+\delta}} ; \tau_x > l \right].
\]

Now note that on the event \( \{\tau_x > l\} \) the random variable \( x + S(l) \in K \). Hence dist\((x_k^+ + S(l), \partial K) \geq Ck^{1/2-\gamma} \). Therefore,
\[
\left| \sum_{l=1}^{k} E[f(x_k^+ + S(l - 1)); \tau_x > l - 1] \right| \leq C \sum_{l=0}^{k-1} E \left[ \frac{|x_k^+ + S(l)|^p_{k^{(1/2-\gamma)(2+\delta)}} ; \tau_x > l} \right] \\
\leq C \sum_{l=0}^{k-1} \frac{|x_k^+|^p + k^{pp/2}}{k^{(1/2-\gamma)(2+\delta)}} \leq C \frac{|x|^p + k^{p(1/2-\gamma)} + k^{pp/2}}{k^{(1/2-\gamma)(2+\delta) - 1}} \\
\leq C \frac{|x|^p + k^{pp/2}}{k^{(1/2-\gamma)(2+\delta) - 1}}. 
\]

Alternative constructions of a harmonic function in a cone
If $p \geq 1$ then, using (2.2) and the fact that $u(x) = 0$ for $x \notin K$, we obtain
\[
E[u(x^+_k + S(\tau_x)); \tau_x \leq k] \leq \mathbb{E}[|x^+_k + S(\tau_x)|^{p-1}\operatorname{dist}(x^+_k + S(\tau_x), \partial K), \tau_x \leq k] \\
\leq Ck^{1/2-\gamma}E[|x^+_k + S(\tau_x)|^{p-1}; \tau_x \leq k] \\
\leq Ck^{p(1/2-\gamma) + Ck^{1/2-\gamma}E[|x + S(\tau_x)|^{p-1}; \tau_x \leq k].
\]
To bound the second term we use the Burkholder inequality,
\[
E[|x + S(\tau_x)|^{p-1}; \tau_x \leq k] \leq C|x|^{p-1} + C\mathbb{E}[\max_{l \leq k}|S(l)|^{p-1}]
\leq C|x|^{p-1} + Ck^{(p-1)/2}.
\]
Then,
\[
E[u(x^+_k + S(\tau_x)); \tau_x \leq k] \leq Ck^{p(1/2-\gamma)} + Ck^{p/2-\gamma} + Ck^{1/2-\gamma}|x|^{p-1}. \tag{5.3}
\]
If $p < 1$ then, applying (2.6), we obtain
\[
E[u(x^+_k + S(\tau_x)); \tau_x \leq k] \leq Ck^{p/2-p\gamma}.
\]
In other words, (5.3) holds also for $p < 1$.
Combining now (5.1), (5.2) and (5.3), we obtain
\[
|E[u(x + S(k)); \tau_x > k] - u(x)| \leq C \left( k^{1/2-\gamma}|x|^{p-1} + k^{p(1/2-\gamma)} + k^{p/2-\gamma} + \frac{|x|^p + k^{p/2}}{k^{(1/2-\gamma)(2+\delta)-1}} \right).
\]
We can assume that $\gamma < 1/2$ is sufficiently small to ensure that $\gamma < p/2$ and $p/2 > (1/2 - \gamma)(2+\delta) - 1 = \delta/2 - 2\gamma - \gamma\delta > 0$.
Then,
\[
\max_{\sqrt{n} \leq k \leq n} |E[u(x + S(k)); \tau_x > k] - u(x)| \\
\leq C \left( n^{1/2-\gamma}|x|^{p-1} + n^{p(1/2-\gamma)} + n^{p/2-\gamma} + n^{p/2-(\delta/2-2\gamma-\gamma\delta)} + \frac{|x|^p}{n^{\delta/4-\gamma-\gamma\delta/2}} \right).
\]
For every $x \in K_{n,\varepsilon}$ one has
\[
|x| \leq 2n^{2\varepsilon}\operatorname{dist}(x, \partial K) \text{ and } \operatorname{dist}(x, \partial K) \geq \frac{1}{2} n^{1/2-\varepsilon}.
\]
Combining these estimates with the lower bound in (2.2), we obtain
\[
|x|^p \leq \frac{2p n^{2\varepsilon}}{C_1} u(x), \tag{5.4}
\]
\[
|x|^{p-1} \leq \frac{2p-1}{C_1} \frac{n^{2(p-1)\varepsilon}}{\operatorname{dist}(x, \partial K)} \leq \frac{2p}{C_1} n^{(2p-1)\varepsilon} \frac{u(x)}{n^{1/2}} \tag{5.5}
\]
and
\[
n^{p/2} \leq 2p n^{p\varepsilon} \left( \operatorname{dist}(x, \partial K) \right)^p \leq \frac{2p}{C_1} u(x)n^{p\varepsilon}. \tag{5.6}
\]
Taking into account (5.4), (5.5) and (5.6), we arrive at the bound
\[
\max_{\sqrt{n} \leq k \leq n} |E[u(x + S(k)); \tau_x > k] - u(x)| \\
\leq Cu(x) \left( n^{(2p-1)\varepsilon-\gamma} + n^{p(\varepsilon-\gamma)} + n^{p\varepsilon-\gamma} + n^{p\varepsilon-(\delta/2-2\varepsilon-\gamma\delta)} + n^{2p\varepsilon-(\delta/4-\gamma-\gamma\delta/2)} \right).
\]
Clearly, we can pick sufficiently small $\varepsilon > 0$ in such a way that all exponents on the right hand side of the previous inequality are negative. This completes the proof of the lemma. □
Alternative constructions of a harmonic function in a cone

Proof of Proposition 5.1. If \( k \in [\sqrt{n}, n] \) then the desired estimate is immediate from Lemma 5.2. Thus, it remains to consider the case \( k < \sqrt{n} \). Clearly,

\[
E[u(x + S(k)); \tau_x > k] - u(x) = E[u(x + S(k)) - u(x); \tau_x > k] - u(x)P(\tau_x \leq k) \tag{5.7}
\]

By the Doob inequality, for every \( x \in \tilde{K}_{n, \varepsilon} \),

\[
P(\tau_x \leq k) \leq P \left( \max_{j \leq k} |S(j)|^2 \geq n^{1-2\varepsilon} \right) \leq C \frac{k}{n^{1-2\varepsilon}}. \tag{5.8}
\]

Using (2.4) and (2.6), we conclude that, for all \( k \leq \sqrt{n} \),

\[
E [u(x + S(k)) - u(x); \tau_x > n] \leq CE \left[ |S(k)||x|^{p-1}1_{\{p \geq 1\}} + |S(k)|^p \right] \leq C \left( n^{1/4} |x|^{p-1} + n^{p/4} \right).
\]

Taking into account (5.5) and (5.6), we obtain

\[
\max_{k \leq \sqrt{n}} E [u(x + S(k)) - u(x); \tau_x > n] \leq \frac{C}{n^q} u(x), \quad x \in \tilde{K}_{n, \varepsilon}. \tag{5.9}
\]

Combining (5.7)–(5.9) completes the proof of the proposition. \( \square \)

Define

\[ \nu_n := \inf \{ n \geq 0 : x + S(n) \in K_{n, \varepsilon} \} \]

and

\[ \tilde{\nu}_n := \inf \{ n \geq 0 : x + S(n) \in \tilde{K}_{n, \varepsilon} \}. \]

**Lemma 5.3.** There exists \( \gamma > 0 \) such that, for every \( x \in K \),

\[
\max_{k \in [n^{1-\varepsilon}, n]} \frac{E [u(x + S(k)); \tau_x > k, \tilde{\nu}_n > [n^{1-\varepsilon}]]}{n^q} \leq \frac{C (1 + |x|^{p-\gamma})}{n^q}.
\]

**Proof.** Set

\[ M(k) := \max_{j \leq k} |x + S(j)| \]

and split the expectation into two parts:

\[
E [u(x + S(k)); \tau_x > k, \tilde{\nu}_n > [n^{1-\varepsilon}]] = E \left[ u(x + S(k)); \tau_x > k, \tilde{\nu}_n > [n^{1-\varepsilon}], M([n^{1-\varepsilon}]) \leq n^{1/2+\varepsilon/2} \right]
\]

\[ + E \left[ u(x + S(k)); \tau_x > k, \tilde{\nu}_n > [n^{1-\varepsilon}], M([n^{1-\varepsilon}]) > n^{1/2+\varepsilon/2} \right]. \tag{5.10}
\]

Set, for brevity, \( m = [n^{1-\varepsilon}] \). Now, using the relation,

\[
\{ \tilde{\nu}_n > m, M(m) \leq n^{1/2+\varepsilon/2} \}
\]

\[ \subset \{ \text{dist}(x + S(j), \partial K) \leq \frac{1}{2} \left( n^{1/2-\varepsilon} + \frac{|x + S(j)|}{n^{2\varepsilon}} \right), |x + S(j)| \leq n^{1/2+\varepsilon/2}, j \leq m \}
\]

\[ \subset \{ \text{dist}(x + S(j), \partial K) \leq n^{1/2-\varepsilon}, j \leq m \} = \{ \nu_n > m \}, \]

we obtain

\[
E \left[ u(x + S(k)); \tau_x > k, \tilde{\nu}_n > n^{1-\varepsilon}, M(m) \leq n^{1/2+\varepsilon/2} \right] \leq E \left[ u(x + S(k)); \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2} \right].
\]
Alternative constructions of a harmonic function in a cone

Now, if $p \geq 1$ then by (2.4),

$$u(x + S(k)) \leq u(x + S(m)) + C|S(k) - S(m)|^p + C|S(k) - S(m)||x + S(m)|^{p-1}.$$  

If $p < 1$ we make use of (2.6) to obtain

$$u(x + S(k)) \leq u(x + S(m)) + C|S(k) - S(m)|^p$$

As a result,

$$u(x + S(k)) \leq u(x + S(m)) + C|S(k) - S(m)|^p + C|S(k) - S(m)||x + S(m)|^{p-1}1\{p \geq 1\}. \quad (5.11)$$

Hence,

$$E \left[u(x + S(k)); \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq E \left[u(x + S(m)); \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$+ C\ E \left[|S(k) - S(m)|^p; \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$+ 1\{p \geq 1\} E \left[|S(k) - S(m)||x + S(m)|^{p-1}; \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right].$$

First, since $u(y) \leq C|y|^p$, by (4.5), we conclude that

$$\max_{k \in [n^{1-\varepsilon}, n]} E \left[u(x + S(m)); \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq Cn^{p/2+\varepsilon/2}P(\tau_x > m, \nu_n > m) \leq Cn^{p/2+\varepsilon/2}e^{-cn^\varepsilon}.$$  

(5.12)

and

$$\max_{k \in [n^{1-\varepsilon}, n]} E \left[|S(k) - S(m)|^p; \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq \max_{k \in [n^{1-\varepsilon}, n]} E \left[|S(k) - S(m)|^p; \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq Cn^{p/2}e^{-cn^\varepsilon}.$$  

(5.13)

Second, for $p \geq 1$ one has by the same argument,

$$\max_{k \in [n^{1-\varepsilon}, n]} E \left[|S(k) - S(m)||x + S(m)|^{p-1}; \tau_x > k, \nu_n > m, M(m) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq Cn^{1/2}n^{(p-1)/2+\varepsilon/2}e^{-cn^\varepsilon}.$$  

(5.14)

Therefore, combining (5.12), (5.13) and (5.14) we obtain, that the first expectation on the right hand side of (5.10) can be estimated as follows,

$$\max_{k \in [n^{1-\varepsilon}, n]} E \left[u(x + S(k)); \tau_x > k, \nu_n > n^{1-\varepsilon}, M([n^{1-\varepsilon}]) \leq n^{1/2+\varepsilon/2}\right]$$

$$\leq Cn^{p/2+\varepsilon/2}e^{-cn^\varepsilon}.$$  

(5.15)

Using (5.11), we have for the second expectation on the right hand side of (5.10),

$$E \left[u(x + S(k)); \tau_x > k, \nu_n > m, M(m) > n^{1/2+\varepsilon/2}\right]$$

$$\leq E \left[u(x + S(m)); \tau_x > m, \nu_n > m, M(m) > n^{1/2+\varepsilon/2}\right]$$

$$+ C\ E \left[|S(k) - S(m)|^p; \tau_x > m, M(m) > n^{1/2+\varepsilon/2}\right]$$

$$+ 1\{p \geq 1\} E \left[|S(k) - S(m)||x + S(m)|^{p-1}; \tau_x > m, M(m) > n^{1/2+\varepsilon/2}\right]$$

$$:= E_1 + E_2 + E_3.$$
Alternative constructions of a harmonic function in a cone

To estimate $E_1$ we apply the upper bound from (2.2), and use the fact that on the event \( \{ \tilde{\nu}_n > m \} \),
\[
\text{dist}(x + S(m), \partial K) \leq \frac{1}{2} \left( n^{1/2-\varepsilon} + \frac{|x + S(m)|}{n^{1/2}} \right).
\]
Then,
\[
E_1 \leq \frac{1}{2} n^{1/2-\varepsilon} E \left[ (x + S(m))^{p-1}; \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right] + \frac{1}{2n^{2\varepsilon}} E \left[ (x + S(m))^p; \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right].
\]
Using independence of increments we obtain
\[
E_2 \leq C n^{p/2} P \left( \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right)
\]
and
\[
E_3 \leq C n^{1/2} E \left[ (x + S(m))^{p-1}; \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right].
\]
Combining these estimates and using the Markov inequality, we obtain
\[
E_1 + E_2 + E_3 \leq \frac{C}{n^{\min(p/2,\varepsilon/2)}} E \left[ (M(m))^p; \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right].
\]
Now note that by Lemma 2.5,
\[
E \left[ (M(m))^p; \tau_x > m, M(m) > n^{1/2+\varepsilon/2} \right] \leq C E[\tau_x \wedge n]. \tag{5.16}
\]
Note that for $p > 2$ the desired statement immediately follows from (2.14). If $p \leq 2$ then, using (2.14),
\[
E[\tau_x \wedge n] \leq n^{1-p/2+\delta/2} E[\tau_x^{p/2-\delta/2}] \leq C (1 + |x|^{p-\delta}) n^{1-p/2+\delta/2}.
\]
By the assumption $E|X|^{2+\delta} < \infty$,
\[
E \left[ |X|^p; |X| > an^{1/2+\varepsilon/2} \right] \leq C n^{-(1/2+\varepsilon/2)(2+\delta-p)}.
\]
Then using directly the last inequality in the proof of Lemma 2.5 we can see that (5.16) remains valid for $p \leq 2$. The proof is complete. \(\square\)

**Remark 5.4.** The only place we need to use the results of [16] is the end of the last Lemma. To make the proof self-contained we can use a different estimate in (5.16). Namely, we can directly use the estimate (2.13) with $t = p$ and then apply estimates $E[\tau_x \wedge n] \leq n$ and further assuming that $E|X|^{p+2} < \infty$ the Markov inequality to probability. This would give the desired estimate in (5.16). Thus we can avoid using the results of [16] by imposing 2 additional moments.

### 5.2 Proof of Theorem 1.1

Fix a large integer $n_0 > 0$ and put, for $m \geq 1$,
\[
n_m = \left[ n_0 (1-c)^{-m} \right],
\]
where $[r]$ denotes the integer part of $r$. Let $n$ be any integer. There exists unique $m$ such that $n \in (n_m, n_{m+1}]$. We first split the expectation into two parts,

Alternative constructions of a harmonic function in a cone

\[ E[u(x + S(n)); \tau_x > n] = E_1(x) + E_2(x) \]
\[ := E[u(x + S(n)); \tau_x > n, \nu_n \leq n_m] + E[u(x + S(n)); \tau_x > n, \nu_n > n_m]. \]

By Lemma 5.3, since \( n_m \geq n^{1-\varepsilon} \), the second term on the right hand side is bounded by

\[ E_2(x) \leq \frac{C(x)}{n_m^{q}}, \]

where

\[ C(x) = C(1 + |x|^{p-q}). \]

For the first term we have

\[ E_1(x) = \sum_{i=1}^{n_m} \int_{K_{n_i}} P(\tilde{\nu}_n = i, \tau_x > i, x + S(i) \in dy) E[u(y + S(n - i)); \tau_y > n - i]. \]

Then, by Proposition 5.1,

\[ E_1(x) \leq \left(1 + \frac{C}{n_i}\right) \sum_{i=1}^{n_m} \int_{K_{n_i}} P(\tilde{\nu}_n = i, \tau_x > i, x + S(i) \in dy) u(y) \]
\[ \leq \left(1 + \frac{C}{n_m}\right) \frac{1}{1 - \frac{C}{n_m}} \sum_{i=1}^{n_m} \int_{K_{n_i}} P(\tilde{\nu}_n = i, \tau_x > i, x + S(i) \in dy) \]
\[ \times E[u(y + S(n_m - i)); \tau_y > n_m - i] \]
\[ = \left(1 + \frac{C}{n_m}\right) \frac{1}{1 - \frac{C}{n_m}} E[u(x + S(n_m)); \tau_x > n_m, \tilde{\nu}_n \leq n_m]. \]

As a result we have

\[ E[u(x + S(n)); \tau_x > n] \leq \left(1 + \frac{C}{n_m}\right) E[u(x + S(n_m)); \tau_x > n_m] + \frac{C(x)}{n_m^{q}}. \] (5.17)

Iterating this procedure \( m \) times, we obtain

\[ \max_{n \in \{n_m, n_m+1\}} E[u(x + S(n)); \tau_x > n] \]
\[ \leq \prod_{j=0}^{m} \left(1 + \frac{C}{n_j}\right) \left( E[u(x + S(n_0)); \tau_x > n_0] + C(x) \sum_{j=0}^{m} n_j^{-q} \right). \] (5.18)

Since \( n_m \) grows exponentially fast, we infer that

\[ \sup_{n} E[u(x + S(n)); \tau_x > n] \leq C(x) < \infty. \] (5.19)
Alternative constructions of a harmonic function in a cone

An identical procedure gives a lower bound
\[ E[u(x + S(n)); \tau_x > n] \geq E_1(x) \]
\[ \geq \frac{1 - \frac{C}{n\kappa}}{1 + \frac{C}{n\kappa}} E[u(x + S(n)); \tau_x > n_m, \tilde{\nu}_n \leq n_m] \]
\[ \geq \frac{1 - \frac{C}{n\kappa}}{1 + \frac{C}{n\kappa}} \left( E[u(x + S(n_m)); \tau_x > n_m] - E[u(x + S(n_m)); \tau_x > n_m, \tilde{\nu}_n > n_m] \right) \]
\[ \geq \frac{1 - \frac{C}{n\kappa}}{1 + \frac{C}{n\kappa}} \left( E[u(x + S(n_m)); \tau_x > n_m] - C(x)n_m^{-q} \right) \]
\[ \geq \prod_{j=0}^{m} \frac{1 - \frac{C}{n\kappa}}{1 + \frac{C}{n\kappa}} E[u(x + S(n_0)); \tau_x > n_0] - C(x) \sum_{j=0}^{m} n_j^{-q}. \quad (5.20) \]

For every positive \( \delta \) we can choose \( n_0 = n_0(\delta) \) such that for all \( m \geq 1, \)
\[ \left| \prod_{j=0}^{m} \frac{1 - \frac{C}{n\kappa}}{1 + \frac{C}{n\kappa}} - 1 \right| \leq \delta \quad \text{and} \quad \sum_{j=0}^{m} n_j^{-q} \leq \delta. \]

Then, for this value of \( n_0 \) and all \( x \in K, \)
\[ \sup_{n > n_0} E[u(x + S(n)); \tau_x > n] \leq (1 + \delta) E[u(x + S(n_0)); \tau_x > n_0] + C(x) \delta \]
and
\[ \inf_{n > n_0} E[u(x + S(n)); \tau_x > n] \geq (1 - \delta) E[u(x + S(n_0)); \tau_x > n_0] - C(x) \delta. \quad (5.21) \]

Consequently,
\[ \sup_{n > n_0} E[u(x + S(n)); \tau_x > n] - \inf_{n > n_0} E[u(x + S(n)); \tau_x > n] \]
\[ \leq 2\delta E[u(x + S(n_0)); \tau_x > n_0] + 2C(x) \delta. \]

Taking into account (5.19) and that \( \delta \) can be made arbitrarily small we conclude that the limit
\[ V(x) := \lim_{n \to \infty} E[u(x + S(n)); \tau_x > n] \]
exists for every \( x \in K \).

For positivity of \( V \) note that by (2.4),
\[ E[u(tx + S_{n_0}); \tau_x > n_0] \geq u(tx) P(\tau_x > n_0) - E[|S_{n_0}|^p] - (t|x|)^{p-1} E[|S_{n_0}|] \]
when \( p \geq 1 \) and by (2.6),
\[ E[u(tx + S_{n_0}); \tau_x > n_0] \geq u(tx) P(\tau_x > n_0) - E[|S_{n_0}|^p] \]
when \( p < 1 \). Also, \( C|x| \leq t^{p-\gamma}|x|^{p-\gamma} \). Hence, it follows from (5.21) that there exists \( R \) such that \( V(x) \) is positive for \( x \in D_{R,\gamma} \). The rest of the proof follows the corresponding part of Lemma 13 of [9]. The proof is complete.
